ABSTRACT

Various lunar gravitational models were evaluated for Apollo mission control using checkpoint techniques developed under CCN 157B, NASA Contract NAS 1-3800. All checkpoints were selected from low inclination Lunar Orbiter missions in order that the results would be applicable to the Apollo missions. Identical techniques were used for each model evaluated in order that relative performance (rapidity of convergence, fit to doppler data, etc.) could be determined.

1.0 PURPOSE

This document reports the work accomplished under Task D of NASA contract NAS 1-7954 concerning lunar gravitational model analysis in support of Apollo mission control.

USE FOR TYPEWRITTEN MATERIAL ONLY

## 2.0 SCOPE

This document is a final report covering all the work done under NASA contract NAS 1-7954, Task D. A thorough analysis of all lunar gravitational models provided has been accomplished using photo checkpoint techniques.

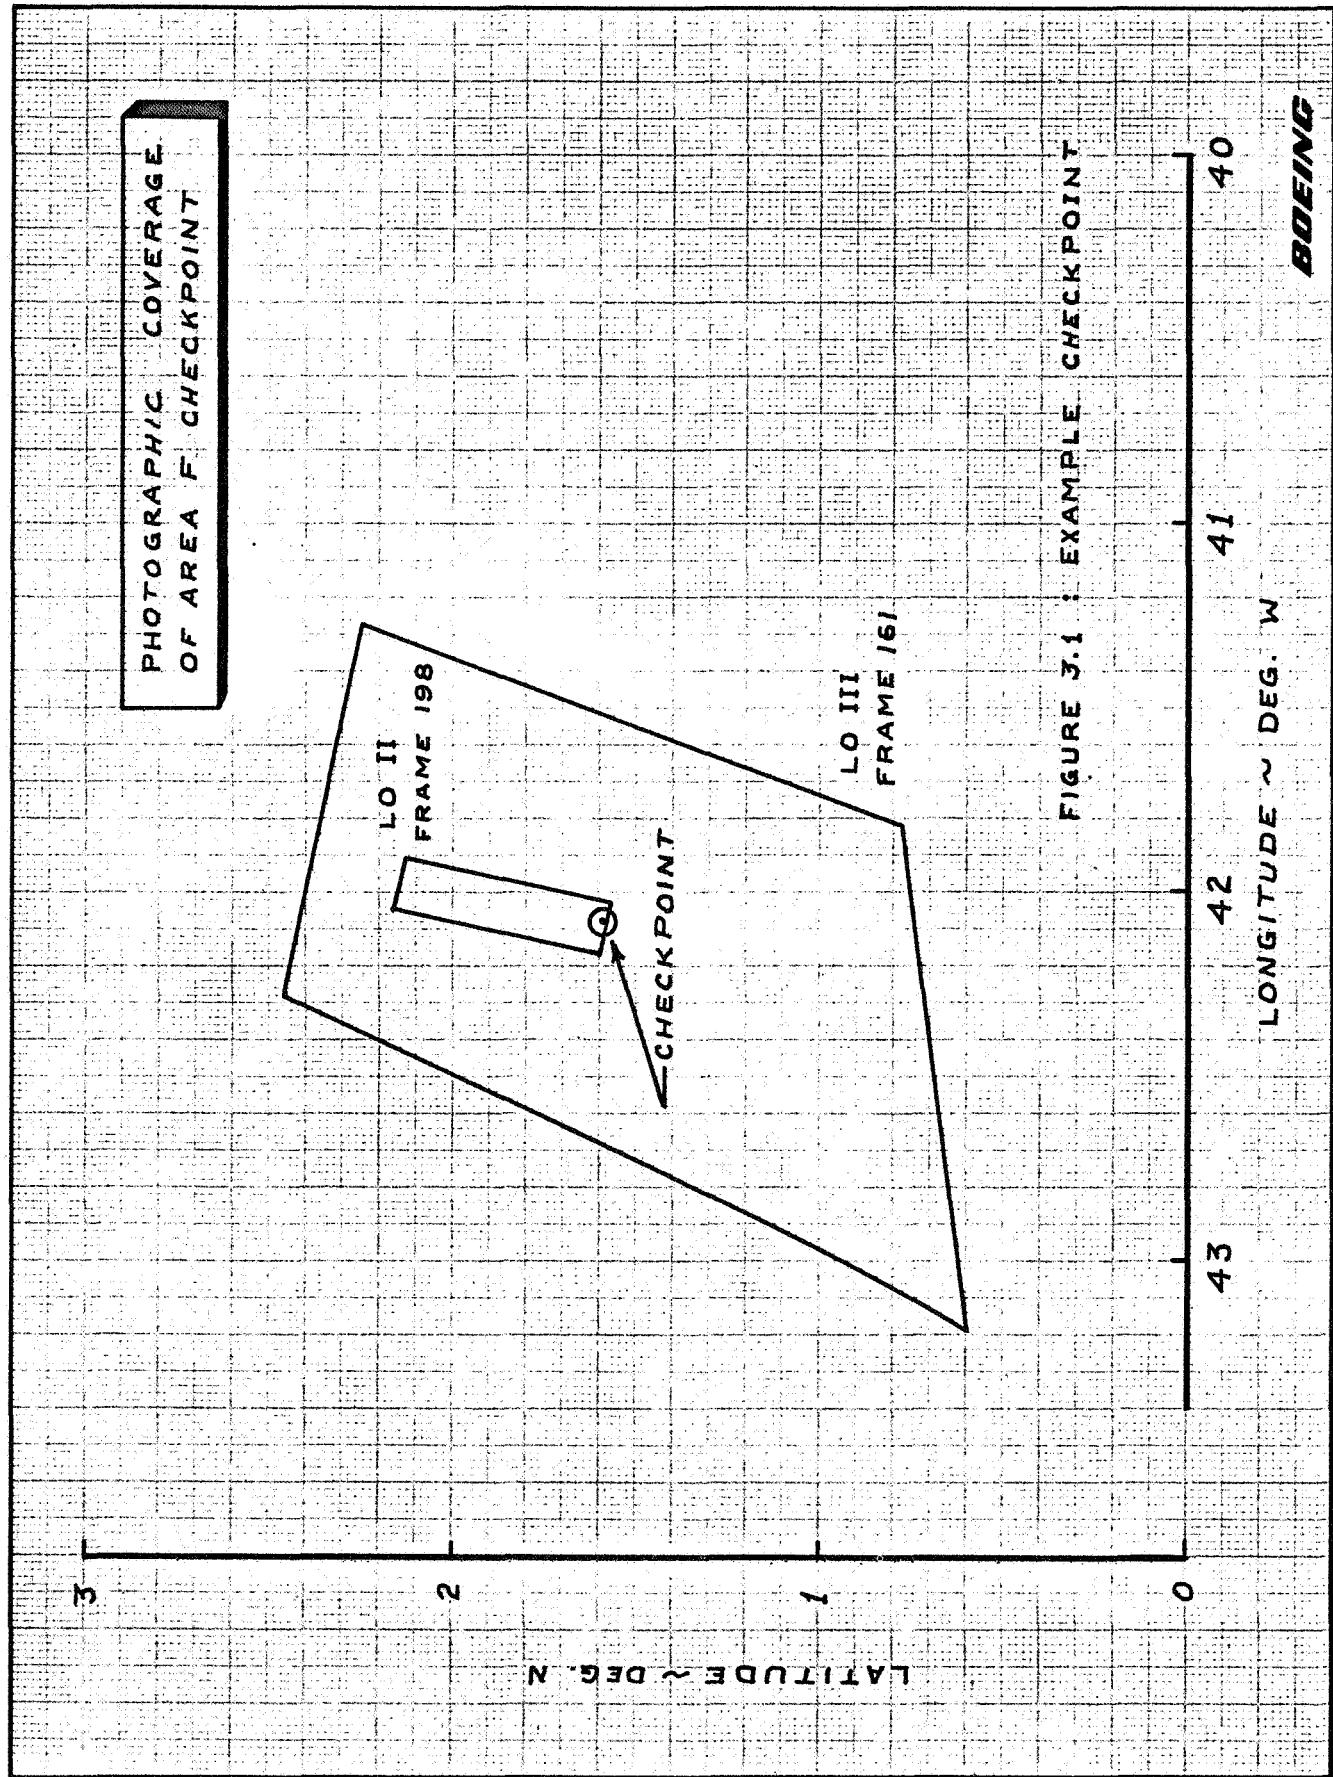

USE FOR TYPEWRITTEN MATERIAL ONLY

## 3.0 INTRODUCTION

The object of this study was to evaluate the capability of various lunar gravitational models to accurately predict spacecraft position within low inclination lunar orbits. The primary method of evaluation consisted of photo checkpoint consistency analysis. A checkpoint is defined as a landmark or feature present in the photographs from at least two Lunar Orbiter missions. A pictorial representation of a checkpoint is shown in Figure 3.1. In this example two telephoto frames are plotted, one from Mission II and the other from Mission III. The checkpoint which is a small crater of about 100 meters diameter was found in both pictures. As indicated, it is on the southern edge of L/O II frame 198 and near the center of LO III frame 161. Using measurements of the checkpoint location on the actual photograph it was possible to compute the selenographic location of the checkpoint. This also required the maneuver angles performed to point the camera and the spacecraft position at shutter actuation as computed by the orbit determination program (ODPL). Since each mission resulted in an independent computation of the checkpoint location it was possible to judge model effectiveness by the closeness of the checkpoint grouping in each area. A more thorough description of the checkpoint technique is given in Reference 1.

Various types of information concerning operation of the orbit determination program are presented to aid in the model evaluations along with checkpoint consistency. These are rapidity of convergence, fit to doppler data and epoch forwarding accuracy. Each of these parameters is important in the process of model selection. Rapid convergence is a necessary requirement for a real time orbit determination technique, due to serious time constraints. A good fit to the doppler data is a requirement since it is the only measurement of the accuracy of the spacecraft state vector that is available. The epoch forwarding capability is one of the more important criteria since orbital maneuvers (orbital transfers and descent maneuvers) must be planned in advance and prediction must be accurate to guarantee mission success.

Included in the model evaluation are two gravitational models developed by Boeing. These models are simple 3 and 4 coefficient models and were developed under Task E of NASM-1-7954. A description of this model development is presented in a companion document (Reference 2).

#### 4.0 LUNAR GRAVITATIONAL MODELS

A total of nine (9) lunar gravitational models were evaluated in this study. These models are summarized in Table 4.0 and described in detail in Tables 4.1 through 4.9. Also indicated in the Tables is the type of data used for the development of the models.

## 5.0 METHOD OF ANALYSIS

## 5.1 CHECKPOINT SELECTION

For this analysis checkpoint locations were selected based on the following criteria:

- periods of two-station coverage (two and three-way doppler data) must be present within the orbit containing the checkpoint photograph,
- checkpoints must be contained in the photographs from two low inclination Lunar Orbiter missions (L/O I, II or III),
- checkpoints should be widely separated on the lunar surface such that orbits with various tracking station viewing geometries could be investigated.

Three checkpoints were used for this analysis and are described in Table 5.1.

## 5.2 MODEL ANALYSIS

The analysis of each specified lunar gravitational model was accomplished in exactly the same manner in order that relative performance could be evaluated. Using the orbit determination program (ODPL) and the tracking data acquired from the first three Lunar Orbiter missions the following technique was used for model analysis:

- compute the spacecraft position at each specified exposure time by processing tracking data with ODPL using data arcs of one and two orbits duration (first orbit includes the exposure time),
- compute the resulting locations on the lunar surface of each of the selected checkpoint features based on the solutions described above.

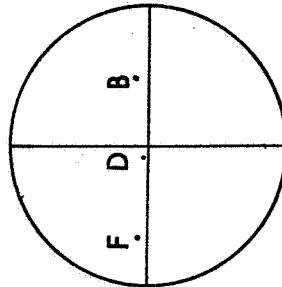

To aid in the determination of the epoch forwarding capability of each model the following technique was used:

- determine spacecraft position using ODPL and tracking data three orbits prior to the exposure time (two and three-way doppler),
- map this solution forward to the selected exposure time with the specified lunar model,
- compute the resulting locations on the lunar surface of each of the selected checkpoint features.

A pictorial description of the procedure is shown in Figure 5.1.

ORBIT DETERMINATION PROCEDURES

## 6.0 RESULTS

The results of this investigation are presented in the form of checkpoint plots which are predicted locations on the lunar surface (longitude and latitude) of the selected checkpoint feature. These checkpoint plots are shown in Figures 6.1 through 6.27 for the three checkpoint areas and the nine gravitational models studied. A key to the symbols used in these figures is given in Table 6.1. The same data in tabular form is presented in Tables 6.2 through 6.9. Also included as supplemental information is the sum of the squares of the doppler residuals resulting from the orbit determination procedure. This is a measure of the accuracy of trajectory prediction based on each lunar model as compared to the actual doppler tracking data received.

Two of the checkpoint plots (Figures 6.4 and 6.5) of area B do not contain a point for a two orbit fit of Mission II data. The orbit determination program would not converge to a solution using the lunar models involved.

It should be noted that the checkpoint location computed from this two orbit fit of Mission II data is not included in the consistency analysis conducted in the following section. It was determined that this solution was in error since for all models studied this point was always far outside the cluster of points resulting from the other solutions (Figure 6.1 through 6.9). No reason for this problem could be found in the tracking data involved in the data fitting procedure but it is obvious that a problem exists based on the results.

All data accumulated during the orbit determination computer runs involved in this study is included in the Appendix of this document. This includes the orbit determination summary reports at both the epoch of the data arc and also at the exposure time. The plots of the doppler residuals for each run are also provided.

## 7.0 MODEL EVALUATION SUMMARY

### 7.1 CONVERGENCE

The method of convergence to a solution (spacecraft position and velocity) using an orbit determination program (ODP) is a measure of model acceptability. During a situation of real time mission control it is necessary that the ODP converge to a solution with certainty and rapidity to guarantee mission success.

Table 7.1 is a summary of the number of iterations necessary to obtain a solution for each of the orbit determinations accomplished in this study. The two columns of numbers under the one and two orbit headings are for the two missions which contain photographs in that checkpoint area. The column titled "Mappings" is the result of the one orbit fits which are mapped forward 3 1/2 orbits to the camera on-time. The average number of iterations to converge is shown in the column on the right. A serious problem exists in Models 4 and 5 in that the two orbit arc for checkpoint area B, Mission II, did not converge. This in necessity eliminates these two models from consideration for Apollo mission control. Based on the information in this table the last three models (7, 8 and 9) are the obvious choice concerning the convergence criteria.

### 7.2 DISPERSIONS

An important consideration for the tasking of lunar model effectiveness is checkpoint consistency. This consistency for each of the models tested is shown in Table 7.2 in the column titled "Maximum Dispersions" (see Figure 7.1). The dispersion tabulated is the distance on the lunar surface between the extreme points on the checkpoint plot which indicate predicted locations of the same lunar feature. The dispersions listed for Models 4 and 5 in checkpoint area B are not realistic values since the orbit determination program did not converge to a solution for the Mission II, two orbit case.

Another test of model effectiveness was to compare the deviations in the mean (see Figure 7.1) between the checkpoint plots generated by each model tested and the results of the photo site accuracy analysis conducted to determine the most accurate estimate of Lunar Orbiter photo locations. This comparison is tabulated in Table 7.2 under the column headed "Deviation in Mean."

The ability of each model to map solutions forward in time is also a serious requirement for the study of model effectiveness. An orbit determination solution was mapped forward 3 1/2 orbits to the camera-on time in order to investigate this mapping capability. The information tabulated in the column titled "Mapping Deviations" (see Figure 7.1) in Table 7.2 is the distance on the lunar surface between the predicted checkpoint location based on the mapping and the best estimate of the checkpoint location resulting from the photo site accuracy analysis.

## 7.2 DISPERSIONS (Continued)

The requirement for an acceptable lunar gravitational model is that the numbers tabulated in all three columns must be small. Any large number indicates some deficiency in the model and therefore its inadequacy for Apollo mission control. Again, Models 7, 8 and 9 appear to stand out as superior to the other models tested.

## 7.3 RANKING

The objective of this study was to determine the best lunar gravitational model (of the nine investigated) for Apollo mission control. The ranking of the models was accomplished using the data discussed in the preceding sections. Table 7.3 presents the ranking of the nine candidate models based on the data available concerning checkpoint consistency, mapping ability and rapidity of convergence.

The last four models in the table are not ranked due to their poor performance and therefore cannot be considered for mission control. This applies especially to the last two models (Model numbers 4 and 5) for which the orbit determination program would not converge to a solution. Model numbers six and three were ranked in fourth and third place respectively due to their poor mapping performance. Models seven and nine were ranked second since they were fair in checkpoint consistency and mapping and also allowed rapid convergence to a solution.

Model number 8 (Boeing R-2) was ranked as the best model considering all the evaluation criteria and also the fact that it consists of only four elements which allows its use in the Apollo onboard computer.

## APPENDIX A

This section contains the reports generated by the orbit determination program (ODPL). For each case there are two reports: one at the epoch of the data arc and the other at the photo time. Section 5.10 of each report specifies the type of report.

The following key will be helpful to determine which case is associated with a given report. In Section 5.1 of the OD report the identification number specifies the case.

An example format of the ID number is:

1B11P

where

- number in first position specifies the Lunar Orbiter mission number
- letter in second position indicates the checkpoint area
- number in third position specifies the Lunar model used
- number in fourth position indicates the number of orbits in the data arc
- letter in the fifth position indicates whether the report is for:

P - photo time within OD data arc

M - OD data arc 3 orbits prior to photo time.
