Introduction

The analysis of series-parallel resistor circuits naturally relies on a firm understanding of both series networks and of parallel networks. For this reason, this tutorial begins with a review of both network types. Kirchhoff’s Laws are also very useful, and in some cases indispensable, for series-parallel analysis and so are reviewed at the start of the tutorial as well. Simply put, series-parallel circuit analysis brings many principles together for the first time.

To review, series-connected components share the same current while parallel-connected components share the same voltage. Kirchhoff’s Voltage Law states that the sum of all voltage rises and voltage drops in any closed path must equal zero. Kirchhoff’s Current Law states that the sum of all currents entering and exiting a node must equal zero. Steady-state power dissipations sum to equal total source power input to any circuit. All of these properties and principles are expressions of fundamental conservation laws (e.g. Conservation of Energy and Conservation of Electric Charge), and all of them find application in series-parallel networks.

Series-parallel networks may be analyzed by collapsing each of the series sub-networks into an equivalent resistance, and each of the parallel sub-networks into an equivalent resistance. As these condensations are made, they must often be repeated, until the entire network is reduced to a single equivalent (“total”) resistance and the source(s). Once voltage or current for the total resistance is computed (using Ohm’s Law), the circuit is then “expanded” step by step into its original form, transferring calculated values of voltage and current to each expanded section based on the properties of series and parallel networks. When all is done, every resistance in the circuit will bear a known voltage and a known current.

Another major topic discussed in the full tutorial is how to check the veracity of mathematical solutions. A common tendency among students is to simply repeat their original steps to see if they obtain the same values again. This is a poor strategy, because certain types of mistakes are easily repeated. In the examples shown in this tutorial, students are encouraged to check their solutions by applying those solution values to different principles (i.e. principles and procedures different from those used to generate the solutions). With this strategy, it is highly unlikely that an incorrect solution will “check” good because that would require complementary errors in both the solution and the solution check.
Series-parallel circuit analysis marks one of the first major hurdles students must clear in their initial studies of electric circuits, being a culmination of several important circuit principles. Series-only and parallel-only circuit analyses tend to pose much less trouble, because the rules of each are static and dependable. When both types of network are combined in the same circuit, however, students are required to carefully decide which rules to apply, and where. In other words, the analysis of series-parallel circuits necessitates the contextual application of general principles whereas series-only and parallel-only circuits are less cognitively demanding.

A strong tendency among the students I’ve taught is a bias toward rote proceduralization: students are quite comfortable memorizing a sequence of steps which they then apply, almost without thinking, to every subsequent problem at hand. I lay the blame for this low level of cognition firmly at the feet of teachers who are more than happy to simply present mathematical solutions to problems without comprehensively explaining why and how that math works. If you are an instructor, recognize that it is your responsibility to buck this trend, and build within your classes a culture of deeper thinking where students are expected to defend the reasons for their analytical steps.

When teaching students these concepts, listen very closely to the questions they ask and their explanations of analytical reasoning. If you hear a student say something like “voltage flows in this direction”, you immediately know that student has a poor grasp of what voltage is\(^1\). If you see a student attempt to define a parallel connection based solely on the fact that current splits at a node, you immediately know that student has a false definition of what a parallel connection is\(^2\).

You will note while reading the tutorial that much emphasis is given to review of these foundational concepts, with consistent emphasis on the “first principles” of physical Conservation laws. The importance of these first principles to the correct understanding of electric circuits cannot be overstated.

\(^1\)This is one of those resilient misconceptions I encounter when teaching electricity and electronics to students. I like to tell instructors and students alike that voltage is the most challenging concept in all of electricity and electronics, and it is very commonly misrepresented in textbooks as a “motive force” or an absolute quantity (i.e. existing at a single point). Rather, voltage is a relative quantity existing between two points. Voltage is the amount of potential energy gained or lost by a unit electrical charge between two locations, and like all expressions of potential energy it is relative between two different states.

\(^2\)Although most parallel connections provide multiple pathways for current to “split”, some parallel connections do no such thing. A good counter-example is a set of three switches (all in the “open” state) connected in parallel: so long as those switches are all open current can move nowhere, but the non-existence of current in no way negates the parallel nature of those switches’ connection to each other! Another counter-example is that of parallel sets of points along a two-conductor cable. Point-pairs belonging to the respective conductors of that cable are parallel to each other (and therefore experience the same voltage) even though no “nodes” exist for current to split. It should be emphasized that these are not academic distinctions, but rather are critically important foundational concepts that if mastered will alleviate many future problems in circuit analysis comprehension. Failing to teach these principles correctly sows the seeds of future confusion.
Difficult concepts for students include the following:

- **Using Ohm’s Law in context.** When applying Ohm’s Law \( V = IR \); \( I = \frac{V}{R} \); \( R = \frac{V}{I} \) to circuits containing multiple resistances, students often mix contexts of voltage, current, and resistance. Whenever applying any equation describing a physical phenomenon, it is important to ensure each variable of that equation relates to the proper real-life value within the problem. For example, when calculating the voltage drop across resistor \( R_2 \), one must be sure that the values for current and resistance are appropriate for that resistor and not some other resistor in the circuit. When calculating \( V_{R_2} \) using the Ohm’s Law equation \( V = IR \), one must use the value of *that resistor’s* current \( (I_{R_2}) \) and *that resistor’s* resistance \( (R_2) \), not some other current and/or resistance value(s). Some students have an unfortunate tendency to overlook context when seeking values to substitute in place of variables in Ohm’s Law problems, and this leads to incorrect results.

- **Voltage being relative between two points.** Unlike current, which may be measured at a single point in a circuit, voltage is fundamentally relative: it only exists as a *difference* between two points. In other words, there is no such thing as voltage existing at a single location. Therefore, while we speak of current going *through* a component in a circuit, we speak of voltage being *across* a component, measured between two terminals on that component. An effective strategy for combating this misconception is to continually apply the correct definition for voltage: *the amount of energy difference between an electric charge carrier at one location versus an identical electric charge carrier at another location*. This concept also reinforces (and is reinforced by) the concept of electric circuit components behaving as sources (infusing charge carriers with energy) or loads (depleting charge carriers of energy).

- **Kirchhoff’s Voltage Law.** Some difficulties with the use of KVL stem from a poor grasp of voltage itself. Unlike current, which may be measured at a single point in a circuit, voltage is fundamentally relative: it only exists as a *difference* between two points. Other difficulties stem from the false notion embraced by some that KVL only applies to a loop including the circuit’s source, when in fact KVL applies to *any closed path* traced through *any* set of electrical components.

- **Respective rules for series versus parallel circuits.** By themselves, series circuits and parallel circuits are relatively easy to analyze, as each has its own set of discrete properties. Things become much more complicated when series and parallel sub-networks become combined into a larger network, as this requires switching from one rule set to the other.

- **Qualitative circuit analysis.** Most students find qualitative analysis of electric circuits much more difficult than quantitative analysis. In other words, it is easier to use a calculator to compute how much current goes through a particular resistor in a circuit than it is to figure out if that current will increase, decrease, or remain the same given a certain change in the circuit. What this requires is a “feel” for how variables in Ohm’s Law and Kirchhoff’s Laws relate to each other, which is a very different skill than numerical calculation. A good way to build this skill is to practice qualitative analysis at every opportunity.
Chapter 2

Case Tutorial

The idea behind a Case Tutorial is to explore new concepts by way of example. In this chapter you will read very little of theory, but by close observation and comparison of the given examples be able to discern patterns and principles much the same way as a scientific experimenter. Hopefully you will find these cases illuminating, and a good supplement to text-based tutorials.

These examples also serve well as challenges following your reading of the other Tutorial(s) in this module – can you explain why the circuits behave as they do?

Each of the following examples provides approximate results as obtained in real experimental circuits. Be aware that similar circuits you build may behave similarly to these, but probably not exactly as these due to unavoidable variations in components and connections. Pay especially close attention to example circuits where undesirable effects occur! Recognizing the error(s) in these examples will help you avoid trouble when building and testing real circuits.
2.1 Example: Battery, lamps, jumper wires, and meters

Here, a large 12 Volt battery and three 12 Volt-rated lamps are provided for experimentation, along with “jumper” wires consisting of plastic-clad stranded copper conductors terminated with spring-loaded “alligator” clip jaws at either end. A simple voltmeter and magnetic ammeter stand ready to take measurements:

Current is the flow of subatomic particles called “electric charge carriers” through electrically conductive materials such as copper metal. We measure current in the metric unit of the Ampere, one Ampere (1 A) being \(6.2415 \times 10^{18}\) individual charge carriers moving past a point in one second of time. Our ammeter senses current by the magnetic field produced around the conductor, a positive indication meaning charge carriers moving (as interpreted by the “conventional flow” standard) with the arrow and a negative indication meaning motion in the opposite direction.

Voltage is the difference in energy for an electric charge carrier experienced at two different locations. We measure voltage in the metric unit of the Volt, one Volt (1 V) being one Joule of energy difference per \(6.2415 \times 10^{18}\) individual charge carriers. Our voltmeter’s two copper-wire test leads will be touched to the two locations of interest, a positive indication meaning charge carriers at the red test lead have more energy than charge carriers at the black test lead; a negative indication means the opposite.

Resistance is the extraction of energy from moving electric charge carriers. We measure resistance in the metric unit of the Ohm, one Ohm (1 Ω) being one Volt of “drop” per Ampere of current.
Connecting two of the three lamps in series with each other results in each lamp glowing dimmer than it ordinarily would if connected to the battery by itself. The measured current in the circuit is also less than expected for a single lamp, and each lamp drops one-half of the battery’s 12 Volts:
Next, the third lamp is connected in parallel to the lower of the two series-connected lamps. The result of this addition is that both lower lamps glow dimmer, and the upper lamp glows brighter. None of the lamps, however, glow as brightly as would be expected when connected to the battery alone:

The upper lamp now drops 8.00 Volts, while each of the lower lamps drops only 4.00 Volts. Current measured near the battery’s positive terminal is greater than it was before, but still not as high as would be expected with the battery powering just a single lamp.

Disconnecting the third lamp returns the circuit to its previous state (with just two lamps connected in series): both lamp voltages return to 6.00 Volts, and current returns to 1.04 Amperes.
Connecting the third lamp in parallel with the upper of the two series-connected lamps results in the two upper lamps dropping 4.00 Volts and the lower lamp dropping 8.00 Volts, and current returning to 1.39 Amperes.

As before, the paralleled lamps are dimmest, while the remaining lamp is brighter.
2.2 Example: Battery and three resistors

In this scenario we will use terminal blocks to neatly organize all wire connections between a battery and three resistors:

Rather than visually show the placement of test equipment in the diagram, measurements will be documented in text form as $V$ and $I$ values$^1$. With the circuit constructed as shown in the above illustration, we obtain the following measurements:

- $V_{AB} = 0.00$ Volts
- $V_{BC} = -3.10$ Volts
- $V_{CD} = 0.00$ Volts
- $V_{DE} = -8.90$ Volts
- $V_{DB} = 3.10$ Volts
- $V_{CA} = 3.10$ Volts
- $V_{EA} = 12.00$ Volts
- $I_A = 4.04$ milliAmperes (conventional flow right to left)
- $I_E = 4.04$ milliAmperes (conventional flow left to right)

$^1$Double-lettered subscripts for $V$ denote the placement of voltmeter test leads, with the first and second letters always representing the red and black test leads respectively. For example, $V_{BC}$ means the voltage measured between terminals B and C with the red test lead touching B and the black test lead touching C. Single-lettered subscripts for $V$ represent the voltmeter’s red test lead, with the black test lead touching a defined “ground” point in the circuit. Current measurements ($I$) imply measurements made at a single location, and so there will only ever be single-lettered subscripts for $I$. Conventional flow notation will be used to specify current direction.
Severing the wire connecting terminals C and D affects most of the measured values:

- $V_{AB} = 0.00$ Volts
- $V_{BC} = 0.00$ Volts
- $V_{CD} = -12.00$ Volts
- $V_{DE} = 0.00$ Volts
- $V_{DB} = 12.00$ Volts
- $V_{CA} = 0.00$ Volts
- $V_{EA} = 12.00$ Volts
- $I_A = 0.00$ milliAmperes
- $I_E = 0.00$ milliAmperes
Severing the wire connecting terminals A and B results in another set of measured values:

- $V_{AB} = -12.00$ Volts
- $V_{BC} = 0.00$ Volts
- $V_{CD} = 0.00$ Volts
- $V_{DE} = 0.00$ Volts
- $V_{DB} = 0.00$ Volts
- $V_{CA} = 12.00$ Volts
- $V_{EA} = 12.00$ Volts
- $I_A = 0.00$ milliAmperes
- $I_E = 0.00$ milliAmperes
2.3 Example: Current source and four resistors

Here, an electronic current source\(^2\), a set of terminal blocks, and several resistors are provided for experimentation. In this case, the current source is configured to output 150 milliAmperes of current.

\[
R_1 = 47 \, \Omega \\
R_2 = 10 \, \Omega \\
R_3 = 120 \, \Omega \\
R_4 = 63 \, \Omega 
\]

Rather than visually show the placement of test equipment in the diagram, measurements will be documented in text form as \(V\) and \(I\) values\(^3\). With the circuit constructed as shown in the above illustration, we obtain the following measurements:

- \(V_{AD} = 8.55\) Volts
- \(V_{EA} = -8.55\) Volts
- \(V_{GE} = 0.00\) Volts
- \(V_{DH} = 6.20\) Volts
- \(V_{GA} = -8.55\) Volts
- \(V_{BC} = 0.00\) Volts
- \(V_{DF} = 6.20\) Volts
- \(I_A = 150.0\) milliAmperes (conventional flow left to right)
- \(I_C = 150.0\) milliAmperes (conventional flow left to right)
- \(I_D = 150.0\) milliAmperes (conventional flow right to left)
- \(I_H\) (at resistor lead) = 98.36 milliAmperes (conventional flow right to left)

\(^2\)Unlike electrochemical batteries which tend to maintain a nearly constant voltage between their terminals over a wide range of current values, a current source maintains a nearly constant current over a wide range of voltages.

\(^3\)Double-lettered subscripts for \(V\) denote the placement of voltmeter test leads, with the first and second letters always representing the red and black test leads respectively. For example, \(V_{BC}\) means the voltage measured between terminals B and C with the red test lead touching B and the black test lead touching C. Single-lettered subscripts for \(V\) represent the voltmeter’s red test lead, with the black test lead touching a defined “ground” point in the circuit. Current measurements (\(I\)) imply measurements made at a single location, and so there will only ever be single-lettered subscripts for \(I\). Conventional flow notation will be used to specify current direction.
Severing the wire connecting terminals D and E affects most of the measured values:

- $V_{AD} = 0.00$ Volts
- $V_{EA} = -$(Maximum) Volts
- $V_{GE} = 0.00$ Volts
- $V_{DH} = +$(Maximum) Volts
- $V_{GA} = -$(Maximum) Volts
- $V_{BC} = 0.00$ Volts
- $V_{DF} = +$(Maximum) Volts
- $I_A = 0.00$ milliAmperes
- $I_C = 0.00$ milliAmperes
- $I_D = 0.00$ milliAmperes
- $I_R$ (at resistor lead) = 0.00 milliAmperes

Note: “Maximum” voltage refers to the *compliance voltage* of the electronic current source: the maximum amount of voltage it is able to muster between its terminals when faced with an open circuit. For most electronic current sources, this will be some modest limit such as 15 Volts or 30 Volts. However, for some high-energy current sources such as *current transformers* used in electric power systems, the maximum open-circuit voltage could actually reach hazardous levels: *hundreds* or even *thousands* of Volts!
A *series-parallel* circuit is one containing both *series* and *parallel* networks. A “series” network is defined by its components being connected in such a way as to form a single path for current (i.e. all components connected in a row). A “parallel” component is defined by its components sharing the same two sets of electrically common points. Both network types are shown here for comparison:

**Series-connected components**

Only one path exists for current

**Parallel-connected components**

These points are electrically common

These points are electrically common

A universal property of *series networks* is that their components share the same amount of continuous current. This is due to the Law of Electric Charge Conservation: electric charge carriers can neither be created nor destroyed, but must always be accounted. The only way for the amount of current entering any point to differ from the amount of current exiting that same point is if charges were to somehow either vanish or come into existence at that point. Since a series circuit is nothing more than a back-to-back collection of points, this principle extends to the series circuit in its entirety.

A universal property of *parallel networks* is that their components share the same amount of voltage. This is due to the Law of Energy Conservation: energy can neither be created nor destroyed, but must always be accounted. The electrical commonality between connected terminals of parallel components ensures those connected points form equipotential surfaces. By definition, charge carriers are free to move along a set of equipotential points without gaining or losing any energy, and therefore any difference in energy between a charge at any point along that equipotential surface and an identical charge at any point along a different equipotential surface must be the same.

A common application of these guarantees is in the connection of electrical meters to measure current and voltage. If we desire to measure current through some component, we must connect our ammeter in *series* with that component to ensure the meter experiences the exact same current as
the component. Likewise, if we desire to measure voltage across some component, we must connect our voltmeter in parallel with that component to ensure the meter experiences the same voltage as the component.

For any network operating under continuous (i.e. steady-state)\footnote{The qualification of “steady state” is important to note, because it is actually possible to have temporary conditions of $P_{in} \neq P_{out}$, such as in circuits containing energy-storing/releasing components such as capacitors, inductors, or secondary-cell batteries.} conditions, be it series, parallel, or a combination of series and parallel, the total power dissipated by the circuit must be equal to the sum of the individual component power dissipations. This is due to the Law of Energy Conservation as well: the continuous flow of energy into any system must equal the continuous flow of energy out of any system.

Kirchhoff’s Laws of voltage and current are important principles for analyzing series-parallel circuits as well. Kirchhoff’s Voltage Law (KVL) states that the algebraic sum of all voltage rises and drops in any loop must be equal to zero. This “loop” may or may not happen to trace an actual path for current in a circuit, as KVL is true regardless of path. KVL is based on the Law of Energy Conservation: when any “test charge” is moved from location to location and eventually back to its starting point, its net energy gain/loss must be zero. This is analogous to a hiker climbing up and down a mountain, gaining potential energy when climbing and losing potential energy when descending: when the hiker returns to their starting altitude, their net total potential energy gain/loss will be zero.

The following example shows KVL applied to a loop formed by test points D-E-F-G-D in a circuit. $V_{DE}$ (0 Volts) plus $V_{FE}$ (−6.6 Volts) plus $V_{GF}$ (10 Volts) plus $V_{DG}$ (−3.4 Volts) equals zero:
Kirchhoff’s Current Law (KCL) states that the algebraic sum of all currents entering and exiting a point (node) in a circuit must be equal to zero. KCL is based on the Law of Electric Charge Conservation: all charges entering must eventually exit.

The following example shows KCL applied to a node in a circuit. By convention, currents entering a node are positive and currents exiting a node are negative, and the ammeter connections are oriented to reflect this standard. $I_1$ (+18 milliAmperes) plus $I_2$ (−6 milliAmperes) plus $I_3$ (−12 milliAmperes) equals zero:
Mastery of these concepts is foundational to successful series-parallel circuit analysis, which consists of representing every series and parallel resistance sub-network in a circuit as equivalent resistances, then repeating this process until the circuit is reduced to a single equivalent resistance. This basic strategy is shown in the following illustration, showing how a five-component series-parallel circuit may be reduced to a single equivalent component in a succession of reducing steps:

The same reduction process is applied to multiple sources, if they exist in the circuit too. At that point, Ohm’s Law may be applied to that single equivalent resistance and to the single source to calculate either voltage or current. Once that is done, the equivalent circuit may be “expanded” step-by-step, transferring all voltage and current values from the simpler version as the properties of series and parallel networks dictate, re-applying various laws (Ohm’s, KVL, KCL) as needed to calculate any unknown voltages or currents. When complete, the all voltages and currents in the circuit’s original form should be known.

An excellent habit to develop when solving any problem is to check your work, with the various properties and laws you’ve learned about circuits being great tools for this purpose. For example, after “collapsing” and then “expanding” a series-parallel circuit to calculate all component voltages and currents, it is a good idea to apply KVL and KCL to the final result as a check of your work: no matter where you apply KVL and/or KCL, all the final results for voltage and current should correctly check.
Series-parallel networks consisting of identical components are relatively easy to analyze. Series networks of identical components exhibit a total resistance equal to one component’s resistance times the number of components; identical sources connected in series (aiding) yield a total voltage equal to one source’s voltage times the number of sources. Likewise, parallel networks of identical components exhibit a total resistance equal to one component’s resistance divided by the number of components; identical sources connected in parallel (aiding) yield a total current equal to one source’s current times the number of sources. When stacked in a series-parallel fashion, these resistance, voltage, and current values compound the same: stacking parallel sub-networks in series with each other yields more resistance and more voltage; stacking series sub-networks in parallel with each other yields less resistance and more current.

This “stacking” technique is commonly employed to construct large arrays of energy sources and energy-storage devices such as photovoltaic solar cells and battery banks.

Voltage divider circuits are series networks, and current divider circuits are parallel networks. When any external load component is connected to either type of divider circuit, the output of that divider circuit will necessarily decrease as a result of that added load. This is due to the fact that adding a load to any simple divider circuit transforms that circuit from a simple-series or simple-parallel network into a series-parallel combination network. The resistance of the connected load combines with the resistance of the divider component connected to the load terminal(s) to form a new equivalent resistance, and this new equivalent resistance value reduces the division ratio that existed prior to the load’s connection.

Connecting a meter to a circuit likewise creates either a series (ammeter) or parallel (voltmeter) sub-network that did not previously exist in the circuit, and “loads” that circuit by extracting a small amount of energy from it. If this newly-formed network converts what was once a simple series or parallel circuit into a series-parallel combination circuit (e.g. connecting a voltmeter in parallel with one component in a series circuit), the result will be that the meter reads slightly less than the true value when unconnected. Voltmeters exhibit very high (but not infinite) resistance, while ammeters exhibit very low (but not zero) resistance, and this means the loading effect should be slight. In either case, the finite resistance of a meter is called its *insertion resistance*.
Chapter 4

Full Tutorial

First, a review of foundational circuit principles.

Three fundamental measures of electricity are voltage \((V)\), current \((I)\), and resistance \((R)\). Voltage is defined as the amount of energy either gained or lost by electric charge carriers between two different locations. Current is defined as the rate of charge carrier flow. Resistance is defined as the amount of voltage drop (i.e. energy lost per charge carrier) for a given amount of current (flow). Ohm’s Law relates these three variables mathematically:

\[
V = IR \quad I = \frac{V}{R} \quad R = \frac{V}{I}
\]

The combination of voltage and current is power \((P)\): the amount of energy either gained or lost per charge carrier multiplied by the number of charge carriers passing through over time equals the rate of energy gained or lost over time. Joule’s Law mathematically relates power to voltage, current, and resistance:

\[
P = IV \quad P = I^2R \quad P = \frac{V^2}{R}
\]

Electrical components designed to boost the energy level of charge carriers passing through are referred to as sources. Components extracting energy from passing charge carriers are called loads. The identity of any component as either a source or a load is evident by comparing the voltage polarity marks versus direction of current. If current enters a component on the “+” side and exits on the “−” side, it means the charge carriers enter at a lower energy level and exit at a higher energy level, which makes that component a source. If current enters a component on the “+” side and exits on the “−” side, it means the charge carriers enter at a higher energy level and exit at a lower energy level, which makes that component a load.

When electrical components are connected together, they form an electrical network. Connections between electrical components may be broadly divided into two categories: series and parallel. Each of these network types exhibits unique properties, and must be thoroughly understood before attempting to understand more complex types of electrical networks.
When electrical components are connected together such that they form a chain providing only one path for current, they are said to be connected in *series* with each other:

![Diagram of components connected in series](image)

With only one path for charge carriers to flow through each component, any continuous flow of electric charge carriers (i.e. current, \( I \)) through each component must be equal due to the Law of Electric Charge Conservation (electric charges can neither be created nor destroyed). Similarly, the Law of Energy Conservation – which states that energy can neither be created or destroyed – informs us that the energy gains or losses of electric charge carriers moving through each component accumulate to equal the total gain or loss in energy for the series network; that is to say, voltages across a set of series-connected components algebraically add to equal the series network’s total voltage. For the same reason, the total resistance (\( R \)) of a series network (defined as the amount of energy lost per charge carrier for a given rate of flow) is equal to the sum of all the individual component and wire resistances. Mathematically stating each of these series network properties:

\[
I_{total} = I_1 = I_2 \cdots = I_n
\]

\[
V_{total} = V_1 + V_2 + \cdots + V_n
\]

\[
R_{total} = R_1 + R_2 + \cdots + R_n
\]

Series connections are used in the measurement of electric current, to ensure the instrument designed to measure electric current (an *ammeter*) will sense the exact same amount of current as the component being tested. A series connection between an ammeter and the component under test guarantees this equality of current:

![Ammeter connected in series](image)

Note that multiple locations are possible for the ammeter – *any* location that is in-line with all components will yield the same measurement of current which is the value of current common to all components in this series network.
When electrical components are connected together such that they share the same two sets of electrically common points (i.e., their respective terminals are made equipotential by direct connection), they are said to be connected in parallel with each other:

The term *equipotential* means no energy is lost or gained by electric charge carriers moving between those connected points. Points connected together by a conductor of negligible resistance will be equipotential by virtue of that conductor’s low resistance. In the parallel network shown above, charge carriers on all the left-hand wires of the network exist at the same potential energy level, as do charge carriers on all the right-hand wires. Therefore, any difference of potential between the left and right wires must be the same. Therefore every component in a parallel network experiences the same potential difference (i.e., same voltage, $V$). In this example, any charge carriers moving from left to right through any of the components will lose the same amount of energy, regardless of which component they happen to pass through.

Current values through each component in a parallel network, however, may differ substantially. In fact, Ohm’s Law ($I = \frac{V}{R}$) guarantees this will be the case if the components in question happen to have differing resistance values ($R$) but all share the same voltage value ($V$). Given the Law of Charge Conservation, we may conclude that the total current for a parallel network must be equal to the algebraic sum of all component (“branch”) currents. Another property of parallel networks is that their total resistance is less than that of the lowest-resistance branch. Mathematically stating each of these parallel network properties:

$$V_{total} = V_1 = V_2 \cdots = V_n$$

$$I_{total} = I_1 + I_2 \cdots + I_n$$

$$R_{total} = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2} \cdots + \frac{1}{R_n}}$$

Parallel connections are used in the measurement of voltage, to ensure the instrument designed to measure voltage (a voltmeter) will sense the exact same amount of voltage as the component being tested. A parallel connection between a voltmeter and the component under test guarantees this equality of voltage.
Note that multiple locations are possible for the voltmeter – touching the voltmeter’s left-hand test lead to any point on the left-hand equipotential zone, and touching the voltmeter’s right-hand test lead to any point on the right-hand equipotential zone, will yield the same measurement of voltage which is the value of voltage common to all components in this parallel network.

A property common to all networks, series and parallel alike, is that total (i.e. source) power is equal to the sum of all load powers in a circuit. This is just an extension of the Law of Energy Conservation (that energy cannot be created or destroyed and so must be accounted for in all cases), because power is nothing more than energy transfer per unit time:

$$P_{\text{total}} = P_1 + P_2 \cdots + P_n$$

This holds true for all circuits operating under steady-state\(^1\) conditions, regardless of shape, because the Law of Energy Conservation is universal.

---

\(^1\)By “steady-state” we mean the quantities of voltage, current, and power remain constant over substantial periods of time. This caveat is based on the fact that energy is always and forever conserved, but power is not necessarily so. Imagine a scenario where a weight is slowly hoisted up to some elevation, and then released so that it falls to the ground: the amount of energy invested in the weight’s ascent is exactly equal to the amount of energy released by the weight as it falls (in the forms of air friction heating, and also energy delivered to the ground upon impact). However, the amount of power expended in slowly hoisting the weight far less than the amount of power delivered by the weight as it slams into the ground, simply due to the disparity in time intervals: the former happens over a long time interval, while the latter occurs over a very brief time interval. An analogous electrical scenario is that of a capacitor slowly energizing to some high voltage level, then rapidly de-energizing into a low-resistance load: the amount of energy invested in the capacitor is precisely equal to the amount of energy later delivered to that load, but the rates of power are quite unequal due to the timespan over which each action takes place. So, when analyzing any circuit operating under steady-state conditions we may regard power as a conserved quantity because everything occurs over the same span of time, but know that it is really energy that is conserved. If the circuit does not operate under steady-state conditions, source power and load power may in fact differ greatly.
Kirchhoff’s Voltage Law (KVL) states that the net change in energy for any charge moved around in a loop – i.e. moved from point to point, returning to the same location where it started – will always be zero. That is to say, as an electric charge gains and loses energy moving between these different points, it must always return to its original energy level after returning to its original location. Since energy gains and losses for electric charges is the definition of voltage, we may express KVL by saying that the algebraic sum of all voltages in a loop equals zero.

If we label points within a loop by letter (e.g. A, B, C, etc.) and denote each voltage within that loop by a letter subscript pair (e.g. \( V_{XY} \), the amount of energy gained or lost by a charge moving from Y to X), KVL becomes evident just by the subscripts. If we move a “test charge” from point A to point B and note the voltage (\( V_{BA} \)), then from point B to point C (\( V_{CB} \)), then all the way around the loop until we return to point A, the sum of those voltages must be the same as the amount of voltage moving from point A to point A (\( V_{AA} \)) – i.e. the amount of voltage between identical points. Of course, this must be equal to zero:

\[
V_{BA} + V_{CB} + V_{nC} \cdots + V_{An} = V_{AA} = 0
\]

KVL is true regardless of the path taken by the charge, as it is an expression of the Law of Energy Conservation (i.e. that energy cannot be created or destroyed, and therefore the amount of energy carried by an electric charge cannot simply appear or vanish, but must be accounted for in every step of that charge’s travels). The path traced need not be in the direction of real current in the circuit, and in fact need not follow any circuit conductors at all. It is perfectly permissible to trace a KVL loop that “jumps” between disconnected points in a circuit. In fact, this is what we often do when applying KVL to the calculation of voltage between points not directly spanned by one component.

Kirchhoff’s Voltage Law (KVL) is useful for calculating unknown voltage values between points in a circuit, if all the other voltage values between points in a loop happen to be known.

Kirchhoff’s Current Law (KCL) states that charge carriers entering a point must exit that point, which is a consequence of the Law of Electric Charge Conservation (i.e. that electric charges cannot be created or destroyed, but must be accounted for in all cases). That is to say, the total amount of current entering a point (or “node”) in a circuit must be the same as the total amount of current exiting that same point. This is true regardless of the number of conductive paths connecting at that point. We may express KCL by saying that the algebraic sum of all currents at a node equals zero:

\[
I_1 + I_2 + I_3 \cdots + I_n = 0
\]

Kirchhoff’s Current Law (KCL) is useful for calculating unknown currents in a circuit, if all the other currents entering and/or exiting a points in the circuit happen to be known.
Now that we have reviewed series and parallel circuits, as well as Kirchhoff’s Laws, let us move on to the topic at hand: series-parallel circuits. As the name implies, these circuits are a blend of series and parallel sections. Consider the following four-resistor circuit which is neither purely series nor purely parallel:

**Original circuit:**

![Original circuit diagram]

An effective method for analyzing any series-parallel resistor circuit consists of applying the principles of series networks and of parallel networks to those portions of the circuit that are series and parallel, respectively, then using the results of those analyses to derive an equivalent of the original circuit using fewer resistors. This process is repeated until the circuit has been condensed to a single resistor representing that circuit’s total resistance. Series and parallel connections will be represented in text form by the symbols $\leftrightarrow$ (series) and $\parallel$ (parallel).

After condensing the original resistor network down to a single equivalent resistor, we may apply Ohm’s Law to the calculation of current and/or voltage (depending on the nature of the source). Once those values have been determined, we may “expand” the single-resistor circuit back to its previous equivalent and apply those calculated values there. After that, we apply Ohm’s Law again to the calculation of voltage and/or current and then transfer those values to the next “expansion” of the circuit and so on until we arrive back at the original circuit configuration with all voltages and currents solved.

If this process sounds tedious to you, know that it certainly can be. However, there are worse problems in life than tedium. Unsolvable problems are certainly worse, and that is what this series-parallel circuit certainly appears to be without analyzing it stage by stage. You should know that a great many analytical problem-solving techniques are nothing more than substitutions of tedium for complexity. By methodically analyzing this series-parallel circuit one sub-network at a time, we exchange its original complexity for a long sequence of relatively simple steps, and that makes it solvable. Effective problem-solvers are patient above all else!

While this problem-solving technique is presented here specifically for series-parallel resistor circuits, it is an expression of a more general problem-solving strategy: solve what you can. A common tendency of students new to any analytical subject is to give up when presented with a problem that they don’t see a complete solution for from the start. Instead, what one should do when presented with a complicated problem is begin by solving what you do know how, even if it is not clear to you how that solution might help you attain a final solution to the problem at hand. As you will see here, applying simple series and simple parallel analysis to portions of the original circuit has the effect of simplifying that circuit, and so with each step the original problem becomes less and less daunting.
We will begin our analysis of this series-parallel circuit by noting which sections (i.e. sub-networks) of it are series and which are parallel, if any\(^3\). Here we see that \( R_1 \) and \( R_2 \) are connected in parallel with each other, as are \( R_3 \) and \( R_4 \). Knowing that parallel-connected resistances result in a diminished total resistance according to the formula \( R_{\text{parallel}} = (R_1^{-1} + R_2^{-1})^{-1} \), we may calculate the equivalent resistance value for \( R_1 \parallel R_2 \) and for \( R_3 \parallel R_4 \):

\[
(R_1 \parallel R_2) = \frac{1}{\frac{1}{1200\,\Omega} + \frac{1}{2700\,\Omega}} = 830.77\,\Omega
\]

\[
(R_3 \parallel R_4) = \frac{1}{\frac{1}{2200\,\Omega} + \frac{1}{790\,\Omega}} = 581.27\,\Omega
\]

**Parallel equivalents:**

---

Once we re-draw the circuit to show each of the parallel sub-networks as single equivalent resistances, the circuit now appears to be a simple series network, much simpler to analyze than before. It should come as no surprise that we should be able to apply this same technique again: identify portions of the circuit that are either simply series or simply parallel and reduce those sub-networks to single equivalent resistors.

---

\(^3\)It is imperative that you have a solid grasp on the definitions of series and parallel networks, so that you may readily recognize series-connected and parallel-connected components within a larger network. Recall that the definition of a series network is one where only a single path exists for current, and that the definition of a parallel network is one where the components connect between the same two points.
Reducing it one more step, knowing that series-connected resistances result in an additive total according to the formula \( R_{\text{series}} = R_1 + R_2 \):

\[
R_{(R_1\parallel R_2)\rightarrow (R_3\parallel R_4)} = 830.77 \, \Omega + 581.27 \, \Omega = 1412.04 \, \Omega
\]

**Series equivalent:**

\[ V_1 \]
\[
\begin{array}{c}
10 \text{ V} \\
\end{array}
\]
\[
(R_1 \parallel R_2) \leftrightarrow (R_3 \parallel R_4)
\]
\[
1412.04 \, \Omega
\]

This single-resistor circuit is obviously not identical to the original four-resistor circuit, but it is *equivalent* in terms of total resistance. And, if the total resistance is the same, then the total current predicted by Ohm’s Law must be the same as well:

\[
I_{\text{total}} = \frac{V_1}{R_{\text{total}}} = \frac{10 \, \text{V}}{1412.04 \, \Omega} = 7.082 \, \text{mA}
\]

It is always a good idea during circuit analysis to annotate your schematic diagrams with calculated values, to provide clear context for those numerical values. Here, we will sketch an arrow showing the calculated total current value of 7.082 mA as well as the 10 Volts impressed across the single equivalent resistor:

**Series equivalent:**

\[ V_1 \]
\[
\begin{array}{c}
10 \text{ V} \\
\end{array}
\]
\[
(R_1 \parallel R_2) \leftrightarrow (R_3 \parallel R_4)
\]
\[
1412.04 \, \Omega
\]
\[
7.082 \, \text{mA}
\]
Now, working our way back to the original circuit configuration, we will examine the equivalent circuit prior to this one to see which values transfer. The previous equivalent circuit was a series configuration, and we know that it is current which is shared among series-connected components. Therefore, it is the 7.082 mA current value we just calculated that may be applied to the previous equivalent circuit:

**Parallel equivalents:**

Ohm’s Law may be applied here to calculate the voltage dropped by each of the two equivalent resistors:

\[ V_{R_1\parallel R_2} = I(R_1 \parallel R_2) = (7.082 \text{ mA})(830.77 \Omega) = 5.883 \text{ V} \]

\[ V_{R_3\parallel R_4} = I(R_3 \parallel R_4) = (7.082 \text{ mA})(581.27 \Omega) = 4.117 \text{ V} \]

Annotating our diagram with these values:

**Parallel equivalents:**
Still working our way back to the original circuit configuration, we examine it to see which of the calculated values from this last analysis will transfer. The original circuit (just one step removed from the last equivalent circuit shown) is a parallel expansion of this circuit’s two resistances. We know that it is voltage which is shared among parallel-connected components, and so we will transfer the 5.883 Volt and 4.117 Volt values to the original circuit:

**Original circuit:**

\[
\begin{align*}
V_1 & \quad 5.883 \text{ V} \\
\text{R}_1 & \quad 1.2 \text{ k}\Omega \\
\text{R}_2 & \quad 2.7 \text{ k}\Omega \\
\text{R}_3 & \quad 2.2 \text{ k}\Omega \\
\text{R}_4 & \quad 790 \Omega \\
\end{align*}
\]

Ohm’s Law may be applied again, this time to calculate current through each individual resistor. Note how we are careful to keep all values in proper context with each other, calculating the current through each resistor by dividing *that resistor’s voltage* by *that resistor’s resistance*:

\[
\begin{align*}
I_{\text{R}_1} &= \frac{V_{\text{R}_1}}{R_1} = \frac{5.883 \text{ V}}{1200 \Omega} = 4.903 \text{ mA} \\
I_{\text{R}_2} &= \frac{V_{\text{R}_2}}{R_2} = \frac{5.883 \text{ V}}{2700 \Omega} = 2.179 \text{ mA} \\
I_{\text{R}_3} &= \frac{V_{\text{R}_3}}{R_3} = \frac{4.117 \text{ V}}{2200 \Omega} = 1.871 \text{ mA} \\
I_{\text{R}_4} &= \frac{V_{\text{R}_4}}{R_4} = \frac{4.117 \text{ V}}{790 \Omega} = 5.211 \text{ mA}
\end{align*}
\]

---

4Mixing contexts is a common way in which students fail to calculate correct results when applying mathematical formulae to physical problems. It is imperative you understand what each and every numerical value means in a circuit, and where it fits. This is the main reason I recommend annotating schematic diagrams with calculated values: to help remind you of those values’ contexts.
Annotating the original schematic diagram with all current values:

**Original circuit:**

![Circuit Diagram]

A wise habit to adopt is checking your solutions, and that is best done by analyzing the results in a different manner than the one by which they were obtained\(^5\). In this case, our calculated values consist of resistor voltage drops and resistor currents. In order to rigorously check these values, we need to apply some principles using voltages and currents other than Ohm’s Law.

Kirchhoff’s Laws provide an excellent means of checking these solutions. We know from Kirchhoff’s Voltage Law (KVL) that the algebraic sum of all voltages in a loop must equal zero. Applying KVL to our analysis by imagining a “test charge” starting at the left-hand conductor of the circuit and progressing around it in a counter-clockwise direction, we will check to see that all the potential gains and losses indeed sum to zero:

\[
(+5.883 \text{ V}) + (+4.117 \text{ V}) + (-10 \text{ V}) = 0 \text{ V}
\]

We know from Kirchhoff’s Current Law (KCL) that the algebraic sum of all currents entering and exiting a node must equal zero. Applying KCL to any of the nodes at the parallel sub-networks, for example at the right-hand node of $R_1 \parallel R_2$ where 7.082 mA enters, 4.903 mA exits, and 2.179 mA also exits:

\[
(+7.082 \text{ mA}) + (-4.903 \text{ mA}) + (-2.179 \text{ mA}) = 0 \text{ mA}
\]

The only analysis left to do at this point is calculate resistor power dissipations, and that may be done in three different ways ($P = IV$, $P = I^2R$, or $P = \frac{V^2}{R}$). For this example I will leave this as an exercise for the reader. Once all resistor power dissipations are calculated, they may be checked by calculating source power ($P = 7.082 \text{ mA} \times 10 \text{ V}$) and verifying that the sum of all resistor powers equals this source power, according to the Conservation of Energy.

---

\(^5\)The novice may see nothing wrong with repeating a set of calculations to ensure none of them were incorrectly computed. However, this naturally leads to a repeat of the same mistakes, if there were any mistakes made. When the checking is done by some means other than the one taken to obtain the original results, common mistakes such as calculator keystroke errors, procedural errors, and other errors prone to repetition are avoided.
Let us analyze a more complex series-parallel circuit in order to see how these same principles may be applied. In this analysis I will omit detailed explanations of every step, and just show the circuit being condensed step-by-step into a single-source and single-resistor equivalent, then expand it step-by-step back to its original form. Each schematic diagram will be fully annotated to show the context of all calculated values.

Here is the original circuit, consisting of two voltage sources and six resistors:

![Circuit Diagram]

It should be evident that $R_1$ and $R_2$ are in parallel with each other, and $R_4$ and $R_5$ are in series with each other.
First equivalent circuit, condensing resistors \( R_1 \) and \( R_2 \) into a parallel equivalent, and resistors \( R_4 \) and \( R_5 \) into a series equivalent:

Now we see that \( R_4 \leftrightarrow R_5 \) is in parallel with \( R_6 \).
Second equivalent circuit, condensing resistors $R_4$, $R_5$, and $R_6$ into a single equivalent:

\[ 
\begin{array}{c}
\text{R}_3 \\
150 \, \Omega \\
\text{V}_1 \\
+ \quad 9 \, \text{V} \\
\text{R}_1 \parallel \text{R}_2 \\
68.75 \, \Omega \\
\text{V}_2 \\
+ \quad 5 \, \text{V} \\
\text{R}_4 \leftrightarrow \text{R}_5 \parallel \text{R}_6 \\
232.47 \, \Omega \\
\end{array} \]

Now it is clear to see that all components are in series with each other, because there is only one path for current between them all. This means we may condense the three resistors into a single equivalent resistor, and the two sources into a single equivalent source.

Our final equivalent circuit will condense all resistors into a single equivalent and both voltage sources into a single source. The two voltage sources are opposing each other, and so the combination of them will be a single source with the stronger source’s polarity and a magnitude equal to the difference in voltage between the two original sources:

\[ 
\begin{array}{c}
\text{V}_1 \leftrightarrow \text{V}_2 \\
+ \quad 4 \, \text{V} \\
\text{R}_3 \leftrightarrow [(\text{R}_4 \leftrightarrow \text{R}_5) \parallel \text{R}_6] \leftrightarrow (\text{R}_1 \parallel \text{R}_2) \\
451.22 \, \Omega \\
\end{array} \]

At this point we are ready to apply Ohm’s Law to the calculation of current, and later to the calculation of individual resistor voltages and currents.
Calculating and annotating current in the final equivalent circuit:

\[ V_1 \leftrightarrow V_2 \quad 4 \text{ V} \quad R_3 \leftrightarrow [(R_4 \leftrightarrow R_5) \parallel R_6] \leftrightarrow (R_1 \parallel R_2) \]

\[ 451.22 \text{ \Omega} \]

\[ 8.865 \text{ mA} \]

Expanding to the second equivalent circuit (series, same current), calculating and annotating resistor voltage drops:

\[ V_1 \leftrightarrow 9 \text{ V} \quad R_3 \quad 150 \text{ \Omega} \]

\[ 8.865 \text{ mA} \quad +1.330 \text{ V} \]

\[ (R_4 \leftrightarrow R_5) \parallel R_6 \]

\[ 232.47 \text{ \Omega} \quad 2.061 \text{ V} \]

\[ 0.610 \text{ V} \quad 8.865 \text{ mA} \]

\[ R_1 \parallel R_2 \]

\[ 68.75 \text{ \Omega} \]

\[ 5 \text{ V} \]
Expanding to the first equivalent circuit (parallel $R_4 \leftrightarrow R_5$ and $R_6$, same voltage), calculating and annotating resistor currents:
Expanding to the original circuit, calculating and annotating resistor currents:

As usual, KVL and KCL offer ways for us to check our work. Here, we may apply KVL to the outer-most loop of the circuit beginning at the upper-left corner and proceeding counter-clockwise. KCL will be applied at both the node below the 9 Volt source and the node to the right of $R_3$. Where and how we apply Kirchhoff’s Laws really doesn’t matter, so long as our application verifies all calculated values of voltage and current:

**KVL, outer loop:** $(+9 \text{ V}) + (-0.610 \text{ V}) + (-5 \text{ V}) + (-2.061 \text{ V}) + (-1.330 \text{ V}) = 0 \text{ V}$

**KCL @ V1 node:** $(8.865 \text{ mA}) + (-2.770 \text{ mA}) + (-6.095 \text{ mA}) = 0 \text{ mA}$

**KCL @ R3 node:** $(4.480 \text{ mA}) + (4.385 \text{ mA}) + (-8.865 \text{ mA}) = 0 \text{ mA}$

Resistor power dissipations may be calculated by applying Joule’s Law in any manner desired ($P = IV$, $P = I^2R$, and/or $P = \frac{V^2}{R}$). As a final check, the sum of all resistor power values must equal the total source power (treating the two sources as a single 4 Volt source carrying 8.865 mA) because the Conservation of Energy in any steady-state scenario means that *power* must be conserved as well.

---

6You will notice that the voltage values shown in the KVL check don’t exact add up to zero, but that is due to rounding. If these voltage values are retained in your calculator’s memory rather than written and re-typed in truncated form, the sum ends up being exactly equal to zero as it should be.

7Alternatively, one could calculate power sourced by $V_1$ and treat $V_2$ as a load, since you will note current is being forced “backward” through $V_2$. 
Some series-parallel networks are much easier to analyze than the examples previously given. If all components in the series and parallel sub-networks are equal in value, the task of calculating equivalent components in the condensed versions of the circuit becomes almost trivial. Take for instance this series-parallel network of batteries for an energy-storage system:

![Series-parallel network diagram]

If each of the batteries outputs 12.6 Volts, and each one has a maximum output current of 35 Amperes, then the array as a whole outputs 37.8 Volts (12.6 Volts times three in series) and may deliver up to 175 Amperes of current to a load (35 Amperes times five in parallel).

A series-parallel resistor “bank” comprised of identical resistors likewise condenses very easily into a single equivalent resistance:

![Series-parallel resistor bank diagram]

If each of these resistors is rated at 100 Ω and 2 Watts, then the combination of three in series yields 300 Ω for each parallel branch, and the combination of four parallel branches diminishes that by a factor of four for a total of 75 Ω. Power ratings simply add up to a total of 24 Watts (12 resistors times 2 Watts each), regardless of the series-parallel configuration, due to the Law of Energy Conservation which stands regardless of circuit shape.
Series-parallel networks may be formed when new components are connected to existing (series-or parallel-only) circuits. One such example is that of loaded voltage divider circuits. As you recall, a “voltage divider” is a network of series-connected resistors intended to divide an applied voltage into smaller proportions. A common application for voltage dividers is to reduce the voltage from a source, down to some level more suitable for a load. A problem faced with such usage of a voltage divider is that once the load is connected to the divider circuit, its voltage division ratio changes by virtue of the load creating a series-parallel network where only a series network existed before.

Take the following voltage divider as an example. With no load connected, its two resistors divide the source voltage into two-thirds and one-third portion, with the lowest third constituting the “output” of the voltage divider. Once a load is connected to the output terminal, though, the output voltage “sags” to a value less than the desired \( \frac{1}{3} \) proportion under the loading effect:

If this voltage divider network is to provide a precise \( \frac{1}{3} \) voltage-division ratio to a load, its resistor values must be selected in anticipation of that load resistance. Only then will the division ratio be correct for the series-parallel network that is formed when the load is attached.

Applying this design strategy to the voltage divider just shown, we could replace the 20 kΩ resistor with a lower-valued resistor, equal to twice the resistance of the 10 kΩ \( \parallel R_{\text{load}} \) parallel sub-network. When calculated, \( 2 \left( (10 \, \text{kΩ})^{-1} + (20 \, \text{kΩ})^{-1} \right)^{-1} = 13.75 \, \text{kΩ} \). With this new upper resistor in place, the voltage divider will supply the desired \( \frac{1}{3} \) ratio (8 Volts from a 24 Volt source) when loaded, but of course will output more than that when unloaded:

It should be noted that the re-designed voltage divider only provides the \( \frac{1}{3} \) voltage division ratio when the load resistance is precisely 22 kΩ. A new load resistance will require another re-design.

Current divider circuits face similar challenges maintaining a desired division ratio when loaded. Just as with voltage dividers, the addition of a load resistance converts what was once a simple (series or parallel) network into a more complex series-parallel network.
This same “loading” problem can occur simply by connecting a meter to a circuit to measure voltage or current. Recall that an ideal voltmeter possesses infinite internal resistance, and that an ideal ammeter possesses zero internal resistance. The purpose of these ideal resistance values is to minimize the amount of energy extracted from the circuit by the meter, because extracting energy alters the operation of the circuit and will yield a measured value different than the true value with the meter absent. In practice it is impossible to measure any quantity without affecting that quantity in any way, but we can minimize the impact any measurement of ours may have.

For example, a voltmeter should have infinite resistance so that no current will pass through it while sensing a voltage. If no charge carriers pass through a voltmeter, none of them will move from a position of higher energy to a position of lower energy, which means no energy will be released by charge carriers to the voltmeter – the voltmeter will simply sense the potential between two points without actually converting any of that potential energy into work.

Likewise, an ammeter should have zero resistance so that current passing through it will not drop any voltage. If no voltage drop occurs, it means charge carriers will have passed through without losing any of their energy – the ammeter will simply sense the flow of charge carriers without forcing them to do any work.

Real voltmeters and ammeters, though, possess finite amounts of resistance called insertion resistance. Digital multimeters in voltage-sensing mode typically exhibit millions of Ohms between their test leads, and DMMs in current-sensing mode typically exhibit just a small fraction of one Ohm. The following resistor network (source omitted) shows the expected loading effects of connected meters:

The voltmeter connected in parallel with $R_3 \leftrightarrow R_4$ forms a new series-parallel sub-network, $R_{\text{voltmeter}} \parallel (R_3 \leftrightarrow R_4)$ having slightly less resistance and therefore dropping slightly less voltage than $R_3 \leftrightarrow R_4$ would on their own. The ammeter connected in series with $R_2$ forms a new series-parallel sub-network, $R_1 \parallel (R_2 \leftrightarrow)$ having slightly greater resistance in the $R_2$ branch which diverts more current through $R_1$ and therefore passes slightly less current than $R_2$ would on its own. In either case, the meter’s loading effect results in a measurement that is falsely low.

Questions

This learning module, along with all others in the ModEL collection, is designed to be used in an inverted instructional environment where students independently read\textsuperscript{1} the tutorials and attempt to answer questions on their own \textit{prior} to the instructor’s interaction with them. In place of lecture\textsuperscript{2}, the instructor engages with students in Socratic-style dialogue, probing and challenging their understanding of the subject matter through inquiry.

Answers are not provided for questions within this chapter, and this is by design. Solved problems may be found in the Tutorial and Derivation chapters, instead. The goal here is \textit{independence}, and this requires students to be challenged in ways where others cannot think for them. Remember that you always have the tools of \textit{experimentation} and \textit{computer simulation} (e.g. SPICE) to explore concepts!

The following lists contain ideas for Socratic-style questions and challenges. Upon inspection, one will notice a strong theme of \textit{metacognition} within these statements: they are designed to foster a regular habit of examining one’s own thoughts as a means toward clearer thinking. As such these sample questions are useful both for instructor-led discussions as well as for self-study.

\textsuperscript{1}Technical reading is an essential academic skill for any technical practitioner to possess for the simple reason that the most comprehensive, accurate, and useful information to be found for developing technical competence is in textual form. Technical careers in general are characterized by the need for continuous learning to remain current with standards and technology, and therefore any technical practitioner who cannot read well is handicapped in their professional development. An excellent resource for educators on improving students’ reading prowess through intentional effort and strategy is the book \textit{Reading For Understanding – How Reading Apprenticeship Improves Disciplinary Learning in Secondary and College Classrooms} by Ruth Schoenbach, Cynthia Greenleaf, and Lynn Murphy.

\textsuperscript{2}Lecture is popular as a teaching method because it is easy to implement: any reasonably articulate subject matter expert can talk to students, even with little preparation. However, it is also quite problematic. A good lecture always makes complicated concepts seem easier than they are, which is bad for students because it instills a false sense of confidence in their own understanding; reading and re-articulation requires more cognitive effort and serves to verify comprehension. A culture of teaching-by-lecture fosters a debilitating dependence upon direct personal instruction, whereas the challenges of modern life demand independent and critical thought made possible only by gathering information and perspectives from afar. Information presented in a lecture is ephemeral, easily lost to failures of memory and dictation; text is forever, and may be referenced at any time.
CHAPTER 5. QUESTIONS

General challenges following tutorial reading

- **Summarize** as much of the text as you can in one paragraph of your own words. A helpful strategy is to explain ideas as you would for an intelligent child: as simple as you can without compromising too much accuracy.

- **Simplify** a particular section of the text, for example a paragraph or even a single sentence, so as to capture the same fundamental idea in fewer words.

- Where did the text make the most sense to you? What was it about the text’s presentation that made it clear?

- Identify where it might be easy for someone to misunderstand the text, and explain why you think it could be confusing.

- Identify any new concept(s) presented in the text, and explain in your own words.

- Identify any familiar concept(s) such as physical laws or principles applied or referenced in the text.

- Devise a proof of concept experiment demonstrating an important principle, physical law, or technical innovation represented in the text.

- Devise an experiment to disprove a plausible misconception.

- Did the text reveal any misconceptions you might have harbored? If so, describe the misconception(s) and the reason(s) why you now know them to be incorrect.

- Describe any useful problem-solving strategies applied in the text.

- Devise a question of your own to challenge a reader’s comprehension of the text.
General follow-up challenges for assigned problems

- Identify where any fundamental laws or principles apply to the solution of this problem, especially before applying any mathematical techniques.

- Devise a thought experiment to explore the characteristics of the problem scenario, applying known laws and principles to mentally model its behavior.

- Describe in detail your own strategy for solving this problem. How did you identify and organized the given information? Did you sketch any diagrams to help frame the problem?

- Is there more than one way to solve this problem? Which method seems best to you?

- Show the work you did in solving this problem, even if the solution is incomplete or incorrect.

- What would you say was the most challenging part of this problem, and why was it so?

- Was any important information missing from the problem which you had to research or recall?

- Was there any extraneous information presented within this problem? If so, what was it and why did it not matter?

- Examine someone else’s solution to identify where they applied fundamental laws or principles.

- Simplify the problem from its given form and show how to solve this simpler version of it. Examples include eliminating certain variables or conditions, altering values to simpler (usually whole) numbers, applying a limiting case (i.e. altering a variable to some extreme or ultimate value).

- For quantitative problems, identify the real-world meaning of all intermediate calculations: their units of measurement, where they fit into the scenario at hand. Annotate any diagrams or illustrations with these calculated values.

- For quantitative problems, try approaching it qualitatively instead, thinking in terms of “increase” and “decrease” rather than definite values.

- For qualitative problems, try approaching it quantitatively instead, proposing simple numerical values for the variables.

- Were there any assumptions you made while solving this problem? Would your solution change if one of those assumptions were altered?

- Identify where it would be easy for someone to go astray in attempting to solve this problem.

- Formulate your own problem based on what you learned solving this one.

General follow-up challenges for experiments or projects

- In what way(s) was this experiment or project easy to complete?

- Identify some of the challenges you faced in completing this experiment or project.
• Show how thorough documentation assisted in the completion of this experiment or project.
• Which fundamental laws or principles are key to this system’s function?
• Identify any way(s) in which one might obtain false or otherwise misleading measurements from test equipment in this system.
• What will happen if (component X) fails (open/shorted/etc.)?
• What would have to occur to make this system unsafe?
5.1 Conceptual reasoning

These questions are designed to stimulate your analytic and synthetic thinking\(^3\). In a Socratic discussion with your instructor, the goal is for these questions to prompt an extended dialogue where assumptions are revealed, conclusions are tested, and understanding is sharpened. Your instructor may also pose additional questions based on those assigned, in order to further probe and refine your conceptual understanding.

Questions that follow are presented to challenge and probe your understanding of various concepts presented in the tutorial. These questions are intended to serve as a guide for the Socratic dialogue between yourself and the instructor. Your instructor’s task is to ensure you have a sound grasp of these concepts, and the questions contained in this document are merely a means to this end. Your instructor may, at his or her discretion, alter or substitute questions for the benefit of tailoring the discussion to each student’s needs. The only absolute requirement is that each student is challenged and assessed at a level equal to or greater than that represented by the documented questions.

It is far more important that you convey your reasoning than it is to simply convey a correct answer. For this reason, you should refrain from researching other information sources to answer questions. What matters here is that you are doing the thinking. If the answer is incorrect, your instructor will work with you to correct it through proper reasoning. A correct answer without an adequate explanation of how you derived that answer is unacceptable, as it does not aid the learning or assessment process.

You will note a conspicuous lack of answers given for these conceptual questions. Unlike standard textbooks where answers to every other question are given somewhere toward the back of the book, here in these learning modules students must rely on other means to check their work. The best way by far is to debate the answers with fellow students and also with the instructor during the Socratic dialogue sessions intended to be used with these learning modules. Reasoning through challenging questions with other people is an excellent tool for developing strong reasoning skills.

Another means of checking your conceptual answers, where applicable, is to use circuit simulation software to explore the effects of changes made to circuits. For example, if one of these conceptual questions challenges you to predict the effects of altering some component parameter in a circuit, you may check the validity of your work by simulating that same parameter change within software and seeing if the results agree.

---

\(^3\) **Analytical** thinking involves the “disassembly” of an idea into its constituent parts, analogous to dissection. **Synthetic** thinking involves the “assembly” of a new idea comprised of multiple concepts, analogous to construction. Both activities are high-level cognitive skills, extremely important for effective problem-solving, necessitating frequent challenge and regular practice to fully develop.
5.1.1 Reading outline and reflections

“Reading maketh a full man; conference a ready man; and writing an exact man” – Francis Bacon

Francis Bacon’s advice is a blueprint for effective education: reading provides the learner with knowledge, writing focuses the learner’s thoughts, and critical dialogue equips the learner to confidently communicate and apply their learning. Independent acquisition and application of knowledge is a powerful skill, well worth the effort to cultivate. To this end, students should read these educational resources closely, write their own outline and reflections on the reading, and discuss in detail their findings with classmates and instructor(s). You should be able to do all of the following after reading any instructional text:

✓ Briefly OUTLINE THE TEXT, as though you were writing a detailed Table of Contents. Feel free to rearrange the order if it makes more sense that way. Prepare to articulate these points in detail and to answer questions from your classmates and instructor. Outlining is a good self-test of thorough reading because you cannot outline what you have not read or do not comprehend.

✓ Demonstrate ACTIVE READING STRATEGIES, including verbalizing your impressions as you read, simplifying long passages to convey the same ideas using fewer words, annotating text and illustrations with your own interpretations, working through mathematical examples shown in the text, cross-referencing passages with relevant illustrations and/or other passages, identifying problem-solving strategies applied by the author, etc. Technical reading is a special case of problem-solving, and so these strategies work precisely because they help solve any problem: paying attention to your own thoughts (metacognition), eliminating unnecessary complexities, identifying what makes sense, paying close attention to details, drawing connections between separated facts, and noting the successful strategies of others.

✓ Identify IMPORTANT THEMES, especially GENERAL LAWS and PRINCIPLES, expounded in the text and express them in the simplest of terms as though you were teaching an intelligent child. This emphasizes connections between related topics and develops your ability to communicate complex ideas to anyone.

✓ Form YOUR OWN QUESTIONS based on the reading, and then pose them to your instructor and classmates for their consideration. Anticipate both correct and incorrect answers, the incorrect answer(s) assuming one or more plausible misconceptions. This helps you view the subject from different perspectives to grasp it more fully.

✓ Devise EXPERIMENTS to test claims presented in the reading, or to disprove misconceptions. Predict possible outcomes of these experiments, and evaluate their meanings: what result(s) would confirm, and what would constitute disproof? Running mental simulations and evaluating results is essential to scientific and diagnostic reasoning.

✓ Specifically identify any points you found CONFUSING. The reason for doing this is to help diagnose misconceptions and overcome barriers to learning.
5.1. Foundational concepts

Correct analysis and diagnosis of electric circuits begins with a proper understanding of some basic concepts. The following is a list of some important concepts referenced in this module’s full tutorial. Define each of them in your own words, and be prepared to illustrate each of these concepts with a description of a practical example and/or a live demonstration.

- Energy
- Conservation of Energy
- Conservation of Electric Charge
- Voltage
- Current
- Resistance
- Electrical source
- Electrical load
- Equipotential points
- Electrically common points
- Ohm’s Law
- Joule’s Law
CHAPTER 5. QUESTIONS

- Properties of series circuits
- Properties of parallel circuits
- Kirchhoff’s Voltage Law
- Kirchhoff’s Current Law
- Series-parallel circuit
- Strategy for analyzing a series-parallel resistor circuit
- Strategies for checking your work
- Voltage divider loading
- Current divider loading
- Voltmeter resistance and loading effect
- Ammeter resistance and loading effect
5.1.3 Electric lamp arrays

Rank these five electric lamp assemblies according to their total electrical resistance (in order from least to greatest), assuming each of the lamps is the same type and rating. Be sure to explain your method of solving this problem:

Challenges

- Identify how the two lamps in assembly C could be joined in parallel with just the addition of one wire.

- Which assembly(ies) will result in the brightest-glowing lamp(s), assuming all are powered by a voltage source of the same value, connected to the two wire ends.

- Identify the brightest-glowing lamp(s) within the three-lamp assemblies D and E.
5.1.4 Identifying series and parallel sub-networks

Examine the following series-parallel resistor circuit and identify components that are connected in series with each other as well as components that are connected in parallel with each other:

Write an expression using series (\(\rightarrow\)) and parallel (\(\parallel\)) symbols representing the total resistance of this circuit as seen from the perspective of the voltage source.

<table>
<thead>
<tr>
<th>Challenges</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Re-write the total resistance expression for a condition where (R_4) is failed shorted.</td>
</tr>
<tr>
<td>• Assuming all resistors are of equal value, which resistor(s) experience the greatest voltage drop?</td>
</tr>
<tr>
<td>• Assuming all resistors are of equal value, which resistor(s) experience the least voltage drop?</td>
</tr>
<tr>
<td>• Identify at least one resistor fault that would cause current to halt through (R_6).</td>
</tr>
</tbody>
</table>
5.1. SERIES AND PARALLEL SUB-NETWORKS WITH A MOVABLE SOURCE

The series- or parallel-connectedness of components may change depending on how a power source is connected to the network. Take this for example:

In the left-hand circuit, resistors $R_2$ and $R_3$ are connected in series with each other as one sub-network, while resistor $R_1$ is in parallel with that series sub-network. In the right-hand circuit, resistors $R_1$ and $R_2$ are connected in series with each other as one sub-network, while resistor $R_3$ is in parallel with that series sub-network.

Write an expression using series ($\leftrightarrow$) and parallel ($\parallel$) symbols representing the total resistance of this circuit as seen from the perspective of the voltage source, for each of the following scenarios:

- Source connected across points A and E =
- Source connected across points F and C =
- Source connected across points D and F =

Challenges

- A very useful problem-solving technique in analyzing series-parallel circuits is to re-draw each circuit with all resistors arranged in the same orientation (i.e. either all horizontal or all vertical). Apply this technique to any of the scenarios described in this problem.
- Explain how it is possible for a pair of resistors to be connected in series with one power supply configuration, and then for those same two resistors to no longer be in series with each other simply by virtue of having moved the power supply and not moving the resistors at all.
5.1.6 Extension cord

A construction crew is working in the basement of a new home, installing insulation, drywall, and other materials necessary to make the basement suitable for habitation. This basement is dark because electric power service has not yet been connected to the home. An engine-driven generator situated in the front yard supplies electricity for temporary lights and power tools used by the construction workers.

This generator has several 120 Volt AC receptacles, into which several extension cords are plugged. At the other end of each cord, multiple receptacles exist for plugging in lights and power tool cords. One of the workers happens to notice that whenever he pulls the trigger on the electric drill he’s using, the portable light next to him (plugged into the same extension cord) dims slightly.

First, draw an equivalent schematic diagram of this circuit, showing the generator as a voltage source, the extension cord as two wires (each one possessing some electrical resistance), and the two loads (portable light and electric drill) connected in parallel with each other.

Next, explain why the work light dims whenever the drill is turned on.

**Challenges**

- Assuming that the generator outputs a constant 120 Volts (AC) under all load conditions, will a work light plugged into a different extension cord also dim when the drill is turned on?

- On a real construction site, *every* load plugged into the same generator will experience some voltage “sag” whenever the drill is turned on, but some more than others. Explain why this is, and identify which load(s) will experience the greatest voltage sag when the drill energizes.
5.1. CONCEPTUAL REASONING

5.1.7 6-Volt to 12-Volt automotive conversion

Antique American automobiles often used 6 Volt electrical systems instead of the 12 Volt components found in more modern cars and trucks. People who restore these old vehicles may have difficulty finding old 6-Volt generators and batteries to replace the defective, original units. An easy solution is to update the vehicle’s generator and battery with modern (12 Volt) components, but then another problem arises.

A 12 Volt generator and 12 Volt battery will overpower the old 6 Volt headlights, brake lights, and other electrical loads in the vehicle. A common solution used by some antique automobile restorers is to connect resistors between the 12-Volt generator system and the 6-Volt loads, like this:

![Resistor Wiring Diagram]

Explain why this solution works, and also discuss some of the disadvantages of using resistors to adapt the new (12 volt) to the old (6 volt) components.

Next, devise a way to re-wire the electrical system of this old automobile so as to not require resistors between the loads and the generator/battery portion of the circuit.

**Challenges**

- Suppose someone mistakenly wired a resistor in series with the fusible link. What ill effect(s) might this cause?
- As it so happens, 6 Volt incandescent lamps are more rugged than 12 Volt incandescent lamps, all other factors being equal. Explain why this is so.
- Explain why using a single resistor rather than one resistor per switch would be a poor circuit design.
5.1.8 Explaining the meaning of calculations

An unfortunate tendency among beginning students in any quantitative discipline is to perform calculations without regard for the real-world meanings of the values, and also to follow mathematical formulae without considering the general principles embodied in each. To ignore concepts while performing calculations is a serious error for a variety of reasons, not the least of which being an increased likelihood of computing results that turn out to be nonsense.

In the spirit of honoring concepts, I present to you a quantitative problem where all the calculations have been done for you, but all variable labels, units, and other identifying data have been stripped away. Your task is to assign proper meaning to each of the numbers, identifying the correct unit of measurement in each case, explaining the significance of each value by describing where it “fits” into the circuit being analyzed, and identifying the general principle employed at each step.

Here is the schematic diagram of the circuit:

```
  R1  390 Ω
   /     |
  /       |
R2  220 Ω
   /     |
  /       |
V_source
```

Here are all the calculations performed in order from first to last:

1. \(390 + 220 = 610\)
2. \((100^{-1} + 130^{-1})^{-1} = 56.52\)
3. \(610 + 56.52 = 666.52\)
4. \(\frac{10}{666.52} = 15.003 \times 10^{-3}\)
5. \((56.52) \times (15.003 \times 10^{-3}) = 0.848\)
6. \((220) \times (15.003 \times 10^{-3}) = 3.301\)
7. \((390) \times (15.003 \times 10^{-3}) = 5.851\)
8. \(5.851 + 3.301 + 0.848 = 10\)
5.1. CONCEPTUAL REASONING

9. \( \frac{0.848}{100} = 8.480 \times 10^{-3} \)
10. \( \frac{0.848}{130} = 6.523 \times 10^{-3} \)
11. \( (8.480 \times 10^{-3}) + (6.523 \times 10^{-3}) = 15.003 \times 10^{-3} \)
12. \( \frac{5.851^2}{390} = 87.79 \times 10^{-3} \)
13. \( \frac{3.301^2}{220} = 49.52 \times 10^{-3} \)
14. \( \frac{0.848^2}{100} = 7.191 \times 10^{-3} \)
15. \( \frac{0.848^2}{130} = 5.532 \times 10^{-3} \)
16. \( 10 \times (15.003 \times 10^{-3}) = 150.033 \times 10^{-3} \)
17. \( (87.79 \times 10^{-3}) + (49.52 \times 10^{-3}) + (7.191 \times 10^{-3}) + (5.532 \times 10^{-3}) = 150.033 \times 10^{-3} \)

Explain what each value means in the circuit, identify its unit of measurement, and identify the general principle used to compute it!

**Challenges**

- Explain how you can check your own thinking as you solve quantitative problems, to avoid the dilemma of just “crunching numbers” to get an answer.

- For each calculated step shown, identify the physical Law or electric circuit principle being applied.

- Identify any of the calculations shown above whose order could be changed. In other words, can this problem be solved in a different order?

- Identify any of the calculations shown above that are not strictly necessary to the complete analysis of the circuit, explaining why it has any merit at all.

- Do you see any alternative paths to a solution, involving specific calculations not shown above?
5.1.9 Bridge networks

Which of these resistor network’s total resistance may be calculated using the analytical tools explained in this module’s full tutorial, and which network is impossible for us to analyze at this stage of our learning?

For the network you can analyze, explain the steps you would take to compute its total resistance. For the network you cannot analyze, explain why it defies simplification.

Challenges

- Devise an experiment to empirically determine the total resistance of each resistor network.
5.2 Quantitative reasoning

These questions are designed to stimulate your computational thinking. In a Socratic discussion with your instructor, the goal is for these questions to reveal your mathematical approach(es) to problem-solving so that good technique and sound reasoning may be reinforced. Your instructor may also pose additional questions based on those assigned, in order to observe your problem-solving firsthand.

Mental arithmetic and estimations are strongly encouraged for all calculations, because without these abilities you will be unable to readily detect errors caused by calculator misuse (e.g. keystroke errors).

You will note a conspicuous lack of answers given for these quantitative questions. Unlike standard textbooks where answers to every other question are given somewhere toward the back of the book, here in these learning modules students must rely on other means to check their work. My advice is to use circuit simulation software such as SPICE to check the correctness of quantitative answers. Refer to those learning modules within this collection focusing on SPICE to see worked examples which you may use directly as practice problems for your own study, and/or as templates you may modify to run your own analyses and generate your own practice problems.

Completely worked example problems found in the Tutorial may also serve as “test cases” for gaining proficiency in the use of circuit simulation software, and then once that proficiency is gained you will never need to rely on an answer key!

---

4In other words, set up the circuit simulation software to analyze the same circuit examples found in the Tutorial. If the simulated results match the answers shown in the Tutorial, it confirms the simulation has properly run. If the simulated results disagree with the Tutorial’s answers, something has been set up incorrectly in the simulation software. Using every Tutorial as practice in this way will quickly develop proficiency in the use of circuit simulation software.

5This approach is perfectly in keeping with the instructional philosophy of these learning modules: teaching students to be self-sufficient thinkers. Answer keys can be useful, but it is even more useful to your long-term success to have a set of tools on hand for checking your own work, because once you have left school and are on your own, there will no longer be “answer keys” available for the problems you will have to solve.
5.2.1 Introduction to spreadsheets

A powerful computational tool you are encouraged to use in your work is a spreadsheet. Available on most personal computers (e.g., Microsoft Excel), spreadsheet software performs numerical calculations based on number values and formulae entered into cells of a grid. This grid is typically arranged as lettered columns and numbered rows, with each cell of the grid identified by its column/row coordinates (e.g., cell B3, cell A8). Each cell may contain a string of text, a number value, or a mathematical formula. The spreadsheet automatically updates the results of all mathematical formulae whenever the entered number values are changed. This means it is possible to set up a spreadsheet to perform a series of calculations on entered data, and those calculations will be re-done by the computer any time the data points are edited in any way.

For example, the following spreadsheet calculates average speed based on entered values of distance traveled and time elapsed:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Distance traveled</td>
<td>46.9</td>
<td>Kilometers</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Time elapsed</td>
<td>1.18</td>
<td>Hours</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Average speed</td>
<td>= B1 / B2</td>
<td>km/h</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Text labels contained in cells A1 through A3 and cells C1 through C3 exist solely for readability and are not involved in any calculations. Cell B1 contains a sample distance value while cell B2 contains a sample time value. The formula for computing speed is contained in cell B3. Note how this formula begins with an “equals” symbol (=), references the values for distance and speed by lettered column and numbered row coordinates (B1 and B2), and uses a forward slash symbol for division (/). The coordinates B1 and B2 function as variables\(^6\) would in an algebraic formula.

When this spreadsheet is executed, the numerical value 39.74576 will appear in cell B3 rather than the formula = B1 / B2, because 39.74576 is the computed speed value given 46.9 kilometers traveled over a period of 1.18 hours. If a different numerical value for distance is entered into cell B1 or a different value for time is entered into cell B2, cell B3’s value will automatically update. All you need to do is set up the given values and any formulae into the spreadsheet, and the computer will do all the calculations for you.

Cell B3 may be referenced by other formulae in the spreadsheet if desired, since it is a variable just like the given values contained in B1 and B2. This means it is possible to set up an entire chain of calculations, one dependent on the result of another, in order to arrive at a final value. The arrangement of the given data and formulae need not follow any pattern on the grid, which means you may place them anywhere.

---

\(^6\)Spreadsheets may also provide means to attach text labels to cells for use as variable names (Microsoft Excel simply calls these labels “names”), but for simple spreadsheets such as those shown here it’s usually easier just to use the standard coordinate naming for each cell.
Common\(^7\) arithmetic operations available for your use in a spreadsheet include the following:

- Addition (+)
- Subtraction (-)
- Multiplication (*)
- Division (/)
- Powers (^)
- Square roots (sqrt())
- Logarithms (ln(), log10())

Parentheses may be used to ensure\(^8\) proper order of operations within a complex formula. Consider this example of a spreadsheet implementing the quadratic formula, used to solve for roots of a polynomial expression in the form of \(ax^2 + bx + c\):

\[
x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}
\]

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(x__1)</td>
<td>((-B4 + \text{sqrt}((B4^2) - (4\times B3\times B5))) / (2\times B3))</td>
</tr>
<tr>
<td>2</td>
<td>(x__2)</td>
<td>((-B4 - \text{sqrt}((B4^2) - (4\times B3\times B5))) / (2\times B3))</td>
</tr>
<tr>
<td>3</td>
<td>(a) =</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>(b) =</td>
<td>5</td>
</tr>
<tr>
<td>5</td>
<td>(c) =</td>
<td>-2</td>
</tr>
</tbody>
</table>

This example is configured to compute roots\(^9\) of the polynomial \(9x^2 + 5x - 2\) because the values of 9, 5, and -2 have been inserted into cells B3, B4, and B5, respectively. Once this spreadsheet has been built, though, it may be used to calculate the roots of any second-degree polynomial expression simply by entering the new \(a\), \(b\), and \(c\) coefficients into cells B3 through B5. The numerical values appearing in cells B1 and B2 will be automatically updated by the computer immediately following any changes made to the coefficients.

\(^7\)Modern spreadsheet software offers a bewildering array of mathematical functions you may use in your computations. I recommend you consult the documentation for your particular spreadsheet for information on operations other than those listed here.

\(^8\)Spreadsheet programs, like text-based programming languages, are designed to follow standard order of operations by default. However, my personal preference is to use parentheses even where strictly unnecessary just to make it clear to any other person viewing the formula what the intended order of operations is.

\(^9\)Reviewing some algebra here, a root is a value for \(x\) that yields an overall value of zero for the polynomial. For this polynomial \((9x^2 + 5x - 2)\) the two roots happen to be \(x = 0.269381\) and \(x = -0.82494\), with these values displayed in cells B1 and B2, respectively upon execution of the spreadsheet.
Alternatively, one could break up the long quadratic formula into smaller pieces like this:

\[
y = \sqrt{b^2 - 4ac} \quad z = 2a
\]

\[
x = \frac{-b \pm y}{z}
\]

Note how the square-root term \(y\) is calculated in cell \(C1\), and the denominator term \(z\) in cell \(C2\). This makes the two final formulae (in cells \(B1\) and \(B2\)) simpler to interpret. The positioning of all these cells on the grid is completely arbitrary\(^{10}\) – all that matters is that they properly reference each other in the formulae.

Spreadsheets are particularly useful for situations where the same set of calculations representing a circuit or other system must be repeated for different initial conditions. The power of a spreadsheet is that it automates what would otherwise be a tedious set of calculations. One specific application of this is to simulate the effects of various components within a circuit failing with abnormal values (e.g. a shorted resistor simulated by making its value nearly zero; an open resistor simulated by making its value extremely large). Another application is analyzing the behavior of a circuit design given new components that are out of specification, and/or aging components experiencing drift over time.

### 5.2.2 Introduction to computer programming

A powerful tool for mathematical modeling is text-based computer programming. This is where you type coded commands in text form which the computer is able to interpret. Many different text-based languages exist for this purpose, but we will focus here on just two of them, C++ and Python.

\(^{10}\)My personal preference is to locate all the “given” data in the upper-left cells of the spreadsheet grid (each data point flanked by a sensible name in the cell to the left and units of measurement in the cell to the right as illustrated in the first distance/time spreadsheet example), sometimes coloring them in order to clearly distinguish which cells contain entered data versus which cells contain computed results from formulae. I like to place all formulae in cells below the given data, and try to arrange them in logical order so that anyone examining my spreadsheet will be able to figure out how I constructed a solution. This is a general principle I believe all computer programmers should follow: document and arrange your code to make it easy for other people to learn from it.
Programm in C++

One of the more popular text-based computer programming languages is called C++. This is a compiled language, which means you must create a plain-text file containing C++ code using a program called a text editor, then execute a software application called a compiler to translate your “source code” into instructions directly understandable to the computer. Here is an example of “source code” for a very simple C++ program intended to perform some basic arithmetic operations and print the results to the computer’s console:

```cpp
#include <iostream>
using namespace std;

int main ()
{
    float x, y;
    x = 200;
    y = -560.5;
    cout << "This simple program performs basic arithmetic on" << endl;
    cout << "the two numbers " << x << " and " << y << " and then" << endl;
    cout << "displays the results on the computer’s console." << endl;
    cout << endl;
    cout << "Sum = " << x + y << endl;
    cout << "Difference = " << x - y << endl;
    cout << "Product = " << x * y << endl;
    cout << "Quotient of " << x / y << endl;
    return 0;
}
```

Computer languages such as C++ are designed to make sense when read by human programmers. The general order of execution is left-to-right, top-to-bottom just the same as reading any text document written in English. Blank lines, indentation, and other “whitespace” is largely irrelevant in C++ code, and is included only to make the code more pleasing to view.

\footnote{Although not included in this example, comments preceded by double-forward slash characters (//) may be added to source code as well to provide explanations of what the code is supposed to do, for the benefit of anyone reading it. The compiler application will ignore all comments.}
Let’s examine the C++ source code line by line to explain what it means:

- **#include <iostream>** and **using namespace std;** are set-up instructions to the compiler giving it some context in which to interpret your code. The code specific to your task is located between the brace symbols ({ and }).

- **int main()** labels the “Main” function for the computer: the instructions within this function (lying between the { and } symbols) it will be commanded to execute. Every complete C++ program contains a main function at minimum, and often additional functions as well. The int declares this function will return an integer number value when complete, which helps to explain the purpose of the return 0; statement at the end of the main function: providing a numerical value of zero at the program’s completion as promised by int. This returned value is rather incidental to our purpose here, but it is fairly standard practice in C++ programming.

- The float declaration reserves places in the computer’s memory for two floating-point variables, in this case the variables’ names being x and y.

- The next two lines assign numerical values to the two variables. Note how each line terminates with a semicolon character (;) and how this pattern holds true for most of the lines in this program.

- All the other instructions take the form of a cout command which prints characters to the “standard output” stream of the computer, which in this case will be text displayed on the console. The double-less-than symbols (<<) show data being sent toward the cout command. Note how verbatim text is enclosed in quotation marks, while variables such as x or mathematical expressions such as x - y are not enclosed in quotations because we want the computer to display the numerical values represented, not the literal text.

- The endl found at the end of every cout statement marks the end of a line of text. If not for these endl inclusions, the text displayed on the computer’s screen would resemble a run-on sentence rather than a paragraph. Note the cout << endl; line, which does nothing but create a blank line on the screen, for no reason other than esthetics.

After saving this source code text to a file with its own name (e.g. myprogram.cpp), you would then compile this source code into an executable file which the computer may then run. If you are using a console-based compiler such as GCC (very popular within variants of the Unix operating system\(^\text{12}\), such as Linux and Apple’s OS X), you would type the following command and press the Enter key:

```
g++ -o myprogram.exe myprogram.cpp
```

This command instructs the GCC compiler to take your source code (myprogram.cpp) and create with it an executable file named myprogram.exe. Simply typing ./myprogram.exe at the command-line will then execute your program:

```
./myprogram.exe
```

\(^{12}\)A very functional option for users of Microsoft Windows is called Cygwin, which provides a Unix-like console environment complete with all the customary utility applications such as GCC!
If you are using a graphic-based C++ development system such as Microsoft Visual Studio\textsuperscript{13}, you may simply create a new console application “project” using this software, then paste or type your code into the example template appearing in the editor window, and finally run your application to test its output.

As this program runs, it displays the following text to the console:

```
This simple program performs basic arithmetic on the two numbers 200 and -560.5 and then displays the results on the computer’s console.

Sum = -360.5
Difference = 760.5
Product = -112100
Quotient of -0.356824
```

As crude as this example program is, it serves the purpose of showing how easy it is to write and execute simple programs in a computer using the C++ language. As you encounter C++ example programs (shown as source code) in any of these modules, feel free to directly copy-and-paste the source code text into a text editor’s screen, then follow the rest of the instructions given here (i.e. save to a file, compile, and finally run your program). You will find that it is generally easier to learn computer programming by closely examining others’ example programs and modifying them than it is to write your own programs starting from a blank screen.

\textsuperscript{13}Using Microsoft Visual Studio community version 2017 at the time of this writing to test this example, here are the steps I needed to follow in order to successfully compile and run a simple program such as this: (1) Start up Visual Studio and select the option to create a New Project; (2) Select the Windows Console Application template, as this will perform necessary set-up steps to generate a console-based program which will save you time and effort as well as avoid simple errors of omission; (3) When the editing screen appears, type or paste the C++ code within the \texttt{main()} function provided in the template, deleting the “Hello World” \texttt{cout} line that came with the template; (4) Type or paste any preprocessor directives (e.g. \texttt{#include} statements, \texttt{namespace} statements) necessary for your code that did not come with the template; (5) Lastly, under the Debug drop-down menu choose either Start Debugging (F5 hot-key) or Start Without Debugging (Ctrl-F5 hotkeys) to compile (“Build”) and run your new program. Upon execution a console window will appear showing the output of your program.
Programming in Python

Another text-based computer programming language called Python allows you to type instructions at a terminal prompt and receive immediate results without having to compile that code. This is because Python is an interpreted language: a software application called an interpreter reads your source code, translates it into computer-understandable instructions, and then executes those instructions in one step.

The following shows what happens on my personal computer when I start up the Python interpreter on my personal computer, by typing python3\(^\text{14}\) and pressing the Enter key:

```
Python 3.7.2 (default, Feb 19 2019, 18:15:18)
[GCC 4.1.2] on linux
Type "help", "copyright", "credits" or "license" for more information.
>>> 
```

The >>> symbols represent the prompt within the Python interpreter “shell”, signifying readiness to accept Python commands entered by the user.

Shown here is an example of the same arithmetic operations performed on the same quantities, using a Python interpreter. All lines shown preceded by the >>> prompt are entries typed by the human programmer, and all lines shown without the >>> prompt are responses from the Python interpreter software:

```
>>> x = 200
>>> y = -560.5
>>> x + y
-360.5
>>> x - y
760.5
>>> x * y
-112100.0
>>> x / y
-0.35682426404995538
>>> quit()
```

\(^{14}\)Using version 3 of Python, which is the latest at the time of this writing.
5.2. QUANTITATIVE REASONING

More advanced mathematical functions are accessible in Python by first entering the line `from math import *` which “imports” these functions from Python’s math library (included on any computer with Python installed). Some examples show some of these functions in use, demonstrating how the Python interpreter may be used as a scientific calculator:

```python
>>> from math import *
>>> sin(30.0)
-0.98803162409286183
>>> sin(radians(30.0))
0.49999999999999994
>>> pow(2.0, 5.0)
32.0
>>> log10(10000.0)
4.0
>>> e
2.7182818284590451
>>> pi
3.1415926535897931
>>> log(pow(e, 6.0))
6.0
>>> asin(0.7071068)
0.78539819000368838
>>> degrees(asin(0.7071068))
45.000001524425265
>>> a = complex(3.0, 4.0)
>>> b = complex(-2.8, 10.5)
>>> a + b
(0.20000000000000018+14.5j)
>>> a - b
(5.8-6.5j)
>>> a * b
(-50.4+20.3j)
>>> a / b
(0.2845287492590397-0.36158861885002963j)
>>> quit()
```

Note how trigonometric functions assume angles expressed in radians rather than degrees, and how Python provides convenient functions for translating between the two. Logarithms assume a base of $e$ unless otherwise stated (e.g. the `log10` function for common logarithms).

The interpreted (versus compiled) nature of Python, as well as its relatively simple syntax, makes it a good choice as a person’s first programming language. For complex applications, interpreted languages such as Python execute slower than compiled languages such as C++, but for the very simple examples used in these learning modules speed is not a concern.
CHAPTER 5. QUESTIONS

Another Python math library is cmath, giving Python the ability to perform arithmetic on complex numbers. This is very useful for AC circuit analysis using phasors15 as shown in the following example. Here we see Python’s interpreter used as a scientific calculator to show series and parallel impedances of a resistor, capacitor, and inductor in a 60 Hz AC circuit:

```python
>>> from math import *
>>> from cmath import *
>>> r = complex(400,0)
>>> f = 60.0
>>> xc = 1/(2 * pi * f * 4.7e-6)
>>> zc = complex(0,-xc)
>>> xl = 2 * pi * f * 1.0
>>> zl = complex(0,xl)
>>> r + zc + zl
(400-187.38811239154882j)
>>> 1/(1/r + 1/zc + 1/zl)
(355.837695813625+125.35793777619385j)
>>> polar(r + zc + zl)
(441.717448903332, -0.4381072059213295)
>>> abs(r + zc + zl)
441.717448903332
>>> phase(r + zc + zl)
-0.4381072059213295
>>> degrees(phase(r + zc + zl))
-25.10169387356105
```

Note how Python defaults to rectangular form for complex quantities. Here we defined a 400 Ohm resistance as a complex value in rectangular form (400 +j0 Ω), then computed capacitive and inductive reactances at 60 Hz and defined each of those as complex (phasor) values (0 −jXc Ω and 0 +jXl Ω, respectively). After that we computed total impedance in series, then total impedance in parallel. Polar-form representation was then shown for the series impedance (441.717 Ω ≈ 25.102°). Note the use of different functions to show the polar-form series impedance value: polar() takes the complex quantity and returns its polar magnitude and phase angle in radians; abs() returns just the polar magnitude; phase() returns just the polar angle, once again in radians. To find the polar phase angle in degrees, we nest the degrees() and phase() functions together.

The utility of Python’s interpreter environment as a scientific calculator should be clear from these examples. Not only does it offer a powerful array of mathematical functions, but also unlimited assignment of variables as well as a convenient text record16 of all calculations performed which may be easily copied and pasted into a text document for archival.

15A “phasor” is a voltage, current, or impedance represented as a complex number, either in rectangular or polar form.
16Like many command-line computing environments, Python’s interpreter supports “up-arrow” recall of previous entries. This allows quick recall of previously typed commands for editing and re-evaluation.
It is also possible to save a set of Python commands to a text file using a text editor application, and then instruct the Python interpreter to execute it at once rather than having to type it line-by-line in the interpreter’s shell. For example, consider the following Python program, saved under the filename myprogram.py:

```python
x = 200
y = -560.5
print("Sum")
print(x + y)
print("Difference")
print(x - y)
print("Product")
print(x * y)
print("Quotient")
print(x / y)
```

As with C++, the interpreter will read this source code from left-to-right, top-to-bottom, just the same as you or I would read a document written in English. Interestingly, whitespace is significant in the Python language (unlike C++), but this simple example program makes no use of that.

To execute this Python program, I would need to type `python myprogram.py` and then press the Enter key at my computer console’s prompt, at which point it would display the following result:

```
Sum
-360.5
Difference
760.5
Product
-112100.0
Quotient
-0.35682426405
```

As you can see, syntax within the Python programming language is simpler than C++, which is one reason why it is often a preferred language for beginning programmers.

If you are interested in learning more about computer programming in any language, you will find a wide variety of books and free tutorials available on those subjects. Otherwise, feel free to learn by the examples presented in these modules.
5.2.3 Programming examples for this topic

Here is an example C++ program intended to display a crude representation of a three-resistor series-parallel circuit and then calculate all relevant voltages, currents, and powers:

```cpp
#include <iostream>
#include <cmath>
using namespace std;

int main ()
{
    float v1, r1, r2, r3, r23, rtotal, ir1, ir2, ir3, vr1, vr2, vr3;
    float pr1, pr2, pr3, ptotal;

    v1 = 240.00;
    r1 = 1.8e3;
    r2 = 2.2e3;
    r3 = 3.3e3;

    cout << "+---V1---R1---+---R2---+ " << endl;
    cout << "| | | " << endl;
    cout << "| +---R3---+ " << endl;
    cout << "| | " << endl;
    cout << "+----------------------+ " << endl;

    cout << "V1 = " << v1 << " Volts" << endl;
    cout << "R1 = " << r1 << " Ohms" << endl;
    cout << "R2 = " << r2 << " Ohms" << endl;
    cout << "R3 = " << r3 << " Ohms" << endl;

    r23 = 1 / ((1 / r2) + (1 / r3));
    rtotal = r1 + r23;

    ir1 = v1 / rtotal;
    vr1 = ir1 * r1;
    vr2 = v1 - vr1;
    vr3 = v1 - vr1;
    ir2 = vr2 / r2;
    ir3 = vr3 / r3;

    cout << "VR1 = " << vr1 << " Volts" << endl;
    cout << "VR2 = " << vr2 << " Volts" << endl;
    cout << "VR3 = " << vr3 << " Volts" << endl;
}
```
cout << "VR3 = " << vr3 << " Volts" << endl;
cout << "IR1 = " << ir1 << " Amperes" << endl;
cout << "IR2 = " << ir2 << " Amperes" << endl;
cout << "IR3 = " << ir3 << " Amperes" << endl;
pr1 = pow(vr1,2) / r1;
pr2 = pow(vr2,2) / r2;
pr3 = pow(vr3,2) / r3;
ptotal = pr1 + pr2 + pr3;
cout << "PR1 = " << pr1 << " Watts" << endl;
cout << "PR2 = " << pr2 << " Watts" << endl;
cout << "PR3 = " << pr3 << " Watts" << endl;
cout << "PTOTAL = " << ptotal << " Watts" << endl;
return 0;
}

When compiled and executed, this program generates the following output:

+---V1---R1----+---R2---+
|        |        |
|        +---R3---+
|        |        |
+------------------+

V1 = 240 Volts
R1 = 1800 Ohms
R2 = 2200 Ohms
R3 = 3300 Ohms
VR1 = 138.462 Volts
VR2 = 101.538 Volts
VR3 = 101.538 Volts
IR1 = 0.0769231 Amperes
IR2 = 0.0461538 Amperes
IR3 = 0.0307692 Amperes
PR1 = 10.6509 Watts
PR2 = 4.68639 Watts
PR3 = 3.12426 Watts
PTOTAL = 18.4615 Watts
5.2.4 Problem-solving example: mixed-source circuit

An excellent type of quantitative problem for students learning to apply Ohm’s Law, Joule’s Law, Kirchhoff’s Laws, and the properties of series and parallel networks is where voltage and current sources coexist within the same circuit, in such a way that all currents are easily defined by those sources. This type of analytical problem forces the problem-solver to carefully consider those fundamental Laws to see where each one fits.

Take for example the following circuit, containing two constant-current elements and two constant-voltage elements. Our task is to calculate all voltages and currents not specified by the component ratings, as well as to determine directions of current, polarities of voltage, and the identity of each component as being either an electrical source or an electrical load:

---

[Diagram of the circuit with labeled components: 4 A, 5 Ω, 9 V, 2 Ω, 3 Ω, 12 V, and 3 A.]

---

17 I hesitate to use the term “source” to describe each, since we often discover one or more of them behaving as loads!
Based on the fact that series-connected elements must share the same continuous current, we may conclude that the 3 Ω resistor has a current of 3 Amperes, and that the 5 Ω resistor and 9 V voltage element both have 4 Amperes through them. We will notate these currents using red-colored arrows to show their directions:

Now that we know the current value through two of the three resistors, we may apply Ohm’s Law \( V = IR \) to each to calculate voltage drops, notating these in blue:

The + and – polarity marks for the resistor voltage drops are placed on the basis of knowing resistors always behave as loads, with charge carriers entering at higher energy (+) and exiting at lower energy (−).

Next, we see an application of Kirchhoff’s Current Law\textsuperscript{19} at the left-hand node, where the 3 Ampere and 4 Ampere currents merge. This results in 7 Amperes of current from left to right through the 12 Volt element and the 2 Ω resistor. Applying Ohm’s Law again to that resistor \((V = IR)\), we calculate its voltage drop to be 14 Volts:

We do not yet know the voltage across each constant-current element, but we may determine this by using Kirchhoff’s Voltage Law\textsuperscript{20}. Stepping around each of the two “loops” in this circuit and summing all the known voltages to determine the unknown voltage necessary to bring that sum to zero:

Lower loop, stepping clockwise starting from lower-left corner:

\[
0 \text{ V} - 12 \text{ V} - 14 \text{ V} - 9 \text{ V} + V_{3A} = 0
\]

\[
V_{3A} = 35 \text{ V}
\]

Upper loop, stepping counter-clockwise starting from lower-left corner:

\[
-12 \text{ V} - 14 \text{ V} + 0 \text{ V} + 9 \text{ V} - 20 \text{ V} + V_{4A} = 0
\]

\[
V_{4A} = 37 \text{ V}
\]

\textsuperscript{19}Another consequence of the Law of Electric Charge Conservation.

\textsuperscript{20}A consequence of the Law of Energy Conservation, that electric charge carriers flowing around a circuit must gain exactly as much energy as they lose.
Adding these voltage notations to the schematic diagram, with polarities shown to make each loop’s sum equal zero:

![Schematic Diagram]

Identifying sources and loads, we simply label as “source” any component where charge carriers enter at lower energy (−) and exit at higher energy (+), and label as “load” any component where charge carriers go from higher to lower energy passing through:
Lastly, we may calculate power for each component using Joule’s Law ($P = IV$):

A good check of our work is to verify that the sum of all source powers equals the sum of all load powers:

$$148\ W + 105\ W + 36\ W = 80\ W + 84\ W + 98\ W + 27\ W$$

$$289\ W = 289\ W$$

Although one may argue that circuits such as this are unrealistic, they provide an excellent practice opportunity to apply all the fundamental laws and properties of circuits: Ohm’s Law, Joule’s Law, Kirchhoff’s Laws, and series/parallel network properties. The basic problem-solving strategy, regardless of circuit shape, is to see where any of these laws or properties apply and then annotate the results of that application, repeating the process until all parameters are solved.

It is worth noting that when students struggle with circuit analysis and/or circuit fault diagnosis, the root cause is more often than not a failure to master these foundational principles. If your comprehension of any of these laws or principles is weak, you will invariably struggle later on, so take the time to absolutely master these!
5.2.5 Building a custom resistance value

Suppose you have a large assortment of fixed-value resistors, with the following resistance values available: 100 Ω, 220 Ω, 270 Ω, 330 Ω, 390 Ω, 470 Ω, 510 Ω, 830 Ω, 1 kΩ. However, what you actually need for a particular project is a 350 Ω resistance.

Describe how you could connect some of the resistors together from your assortment to create a single resistance of 350 Ω.

**Challenges**

- If each of these resistors is rated at $\frac{1}{4}$ Watt power dissipation, determine the maximum amount of power your proposed network will be able to dissipate without damage.

- Assuming individual resistor tolerances of ±5%, calculate the highest and lowest possible resistance values for your network.
5.2.6 Two different LED circuits

Suppose we wish to power three light-emitting diodes (LEDs), each one rated at 1.6 Volts and 20 milliAmperes, with a single 6 Volt battery. We have two different ways of doing this, one way connecting the three LEDs in series and the other connecting the three LEDs in parallel with each other:

Calculate the necessary resistor value for each of these circuits to limit each LED’s current to 20 mA:

\[ R_1 = \]

\[ R_2 = \]

Which of these two circuits will be the most energy-efficient, making the best use of the battery’s energy to produce light, and wasting the least amount of energy in the form of heat?

**Challenges**

- Calculate the power dissipated by each resistor.
- Suppose one of the LEDs fails open in each of the circuits. Predict the effect of this fault in each of the circuit configurations.
- Suppose one of the LEDs fails shorted in each of the circuits. Predict the effect of this fault in each of the circuit configurations.
5.2.7 Four-resistor circuit

Calculate all voltages and currents in this circuit, given only the resistor values and the source value:

$$\begin{array}{c}
1 \text{k}\Omega \\
R_1 \\
R_2 \\
R_3 \ 150 \Omega \\
R_4 \ 450 \Omega \\
\end{array}$$

$$\begin{array}{c}
500 \Omega \\
\text{Source} \\
11 \text{V} \\
\end{array}$$

**Challenges**

- Apply Kirchhoff’s Voltage Law to the R1-R2-Source loop of the circuit, proving the sum of those voltages equals zero.

- Apply Kirchhoff’s Voltage Law to the R3-R4-Source-R2 loop of the circuit, proving the sum of those voltages equals zero.

- Apply Kirchhoff’s Current Law to the node below the source, proving the sum of currents entering and exiting the node equals zero.
5.2.8 Five-resistor circuit

Calculate all voltages and currents in this circuit, given only the resistor values and the source value:

\[ \begin{align*}
R_1 & = 790 \, \Omega \\
R_2 & = 8.6 \, k\Omega \\
R_3 & = 1 \, k\Omega \\
R_4 & = 2.2 \, k\Omega \\

**Challenges**

- Apply Kirchhoff’s Voltage Law to the R1-R2-Source loop of the circuit, proving the sum of those voltages equals zero.
- Apply Kirchhoff’s Voltage Law to the R2-R3-Source loop of the circuit, proving the sum of those voltages equals zero.
- Apply Kirchhoff’s Current Law to the node lower-left, proving the sum of currents entering and exiting the node equals zero.
- Explain what would happen if the diagonal wire were severed.
5.2.9 Terminal-block resistor circuit

*Terminal blocks* are mechanical assemblies using screws or spring-clips to secure connections to metal wires and component leads, commonly used in industrial circuit to organize wire connections and facilitate quick alterations of circuit connections. The following photograph shows a typical terminal block installation in an industrial wiring panel:

Note how each of the terminal blocks is uniquely numbered, and how many of the wires entering the left-hand side of each block bears a label identifying which terminal it should be connected to (e.g. “TB1-4” means terminal number 4 of terminal block assembly TB1). Another photograph shows a different style of terminal block, using spring clips rather than screws to clamp wire-ends to the metal bar inside of each terminal block:
In this next image, we see five resistors attached to ten terminal blocks, the left-hand side of each terminal block ready to receive “jumper” wires to connect these resistors to each other to form a network:

Write a list of necessary “jumper” wire connections to make between these numbered terminal blocks in order to create the following series-parallel circuit, then calculate all resistor voltage drops assuming each resistor is 1000 Ω in value:

Next, apply Kirchhoff’s Voltage Law to the voltages within the loop represented by the terminal sequence 0-2-5-4-0. In other words, tally the voltage gains and losses as an imaginary “test charge” is moved from terminal 0 to terminal 2 to terminal 5 to terminal 4 to terminal 0 in this resistor network.

Lastly, determine $V_{7-1}$ following the convention that the voltmeter’s red test lead contacts the first subscripted test point and the black test lead contacts the second.
5.2. QUANTITATIVE REASONING

Challenge

• A useful problem-solving technique when designing circuits to be constructed on a terminal block is to label the components in a schematic diagram with terminal numbers. Do that for this problem, and show how this step simplifies the process of identifying where to place connecting “jumper” wires.

• Identify a single resistor fault that will make $V_{R1} = 0$ Volts.

• Identify a single resistor fault that will make $V_{R3} = 6$ Volts.
5.2.10 Mixed-source circuits

The following circuits contain a combination of constant-voltage and constant-current components. Constant-voltage components, of course, maintain the same voltage for all current conditions while constant-current components maintain the same current for all voltage conditions. While these constant-parameter components are commonly referred to as sources, it should be realized that they may in fact behave as loads if overpowered by another source.

Based on this knowledge, as well as Ohm’s Law, Kirchhoff’s Laws, and other foundational principles of electric circuits, determine all component voltages and component currents in the following circuits, being sure to specify the polarity (+, −) of each voltage and the direction (conventional flow notation) of each current. Also, explain how you used your knowledge of fundamental circuit principles to determine each of these parameters:

Circuit #1

\[
\begin{align*}
I_{V1} &= \\
V_{R1} &= \\
I_{R1} &= \\
V_{R2} &= \\
I_{R2} &= \\
V_{I1} &=
\end{align*}
\]
Circuit #2

- $I_{V1} = \hphantom{0}$
- $V_{I1} = \hphantom{0}$
- $V_{I2} = \hphantom{0}$
- $V_{R1} = \hphantom{0}$
- $I_{R1} = \hphantom{0}$
- $V_{R2} = \hphantom{0}$
- $I_{R2} = \hphantom{0}$
Circuit #3

\[ I_1 = 2 \text{ A} \]
\[ V_{I1} = 10 \text{ V} \]

**Challenges**

- What would happen if two voltage sources of differing voltage ratings were connected directly in parallel with each other, with matching polarities?

- What would happen if two current sources of differing current ratings were connected directly in series with each other, with matching current directions?
5.2.11 More mixed-source circuits

The following circuits contain a combination of constant-voltage and constant-current components. Constant-voltage components, of course, maintain the same voltage for all current conditions while constant-current components maintain the same current for all voltage conditions. While these constant-parameter components are commonly referred to as sources, it should be realized that they may in fact behave as loads if overpowered by another source.

Based on this knowledge, as well as Ohm’s Law, Kirchhoff’s Laws, and other foundational principles of electric circuits, determine all component voltages and component currents in the following circuits, being sure to specify the polarity (+, −) of each voltage and the direction (conventional flow notation) of each current. Use this information to determine whether each component functions as a source or as a load. Also, explain how you used your knowledge of fundamental circuit principles to determine each of these parameters:

Challenges

- What does it mean for a constant-voltage or constant-current component to behave as a source?
5.2. QUANTITATIVE REASONING

- What does it mean for a constant-voltage or constant-current component to behave as a load?
- Modify any single component value and determine the effect(s) of that change on all voltages, currents, and source/load determinations.

5.2.12 Circuit with unknown source value

Calculate all voltages and currents in this circuit, given only the resistor values and one of the current values:

Challenges

- Identify the effect on $I_{R2}$ if resistor $R_3$ happens to fail open.
- Identify the effect on $V_{R1}$ if resistor $R_4$ happens to fail shorted.
- Identify the effect on $V_{R1}$ if resistor $R_5$ happens to fail open.
- Identify the effect on $V_{R4}$ if resistor $R_5$ happens to fail shorted.
- Demonstrate how to apply Kirchhoff’s Voltage Law in this circuit, once you have obtained values for all voltages and currents.
- Demonstrate how to apply Kirchhoff’s Current Law in this circuit, once you have obtained values for all voltages and currents.
5.2.13 Incorrect voltmeter readings

Suppose you constructed a simple two-resistor voltage divider using identical 1 MΩ resistors, powered by a source voltage of exactly 15 Volts. Measuring voltage across each resistor using a digital multimeter (DMM), one at a time, you obtain equal measurements of 7.200 Volts.

This, of course, is less than the perfect 7.500 Volts one would expect across each resistor of such a simple voltage divider. Explain why the voltmeter gives less-than-perfect measurements of resistor voltage, and calculate the voltmeter’s internal resistance based on this measurement.

Challenges

- How can we tell that the 7.200 Volt reading was not due to imperfections in the resistors?
5.2.14 Interpreting a SPICE analysis

A computer program called SPICE was developed in the early 1970’s, whereby a text-based description of an electric circuit (called a netlist) could be entered into a computer, and then computer would be directed to apply fundamental laws of electric circuits to the netlist circuit description according to algorithms coded in SPICE.

A netlist specifying the circuit to SPICE is shown here, followed by a schematic diagram (for illustrative purposes only, not for the computer running SPICE) showing all the numbered “nodes” which SPICE uses to define connection points between components:

* Five-resistor series-parallel DC circuit

\[
\begin{align*}
\text{v1} & : 1 \quad 0 \quad \text{dc} \quad 7 \\
\text{r1} & : 1 \quad 2 \quad 4700 \\
\text{r2} & : 2 \quad 3 \quad 3300 \\
\text{r3} & : 3 \quad 5 \quad 2700 \\
\text{r4} & : 3 \quad 4 \quad 2200 \\
\text{r5} & : 4 \quad 6 \quad 1000 \\
\text{vamm1} & : 5 \quad 0 \\
\text{vamm2} & : 6 \quad 0 \\
\text{.dc} & \text{ v1} \quad 7 \quad 7 \quad 1 \\
\text{.print} & \text{ dc v(1,2) v(2,3) v(3,4)} \\
\text{.print} & \text{ dc v(3,5) v(4,6) i(v1)} \\
\text{.print} & \text{ dc i(vamm1) i(vamm2)} \\
\text{.end} \\
\end{align*}
\]

Note: this schematic diagram is shown only for your benefit. The computer running SPICE software needs only a text "netlist" to describe the circuit, not a graphical image!

Note the inclusion of zero-voltage sources \text{vamm1} and \text{vamm2}, used in this netlist as ammeters for the purpose of measuring current through \( R_3 \) and \( R_4 \leftrightarrow R_5 \), respectively. Legacy versions of SPICE
could only analyze currents through voltage sources, and so if one needed an ammeter placed in a SPICE circuit, the solution was to insert a zero-voltage source to prompt SPICE to report the amount of current through it.

Identify how each component’s connecting nodes and essential parameters (i.e. values) are specified in the netlist. Based on the what you can identify in this netlist, perform your own calculations using Ohm’s Law to predict all other values in this circuit.

When SPICE (software version 2G6) processes the contents of this “netlist” file, it outputs a text description of the analysis. The following text has been edited for clarity (e.g. blank lines, extraneous characters, and statistical data removed):

```
v1     v(1,2)     v(2,3)     v(3,4)
7.000E+00 3.476E+00 2.441E+00 7.446E-01
```

```

```

```
v1     i(vamm1)     i(vamm2)
7.000E+00 4.011E-04 3.385E-04
```

The same netlist processed by a more modern version of SPICE (NGSPICE version 26) produces the following analysis:

Interpret the output of SPICE to the best of your ability. Identify all parameters that you can, and see if the results of the computer’s analysis agree with your own calculations.

Once you become familiar with the analysis data format of SPICE, you will be able to use the “Gallery” of SPICE simulations found in the “SPICE Modeling of Resistor Circuits” module as practice problems for developing your own circuit analysis skills. If you become proficient with creating your own netlists and running SPICE simulations, your freedom to create practice problems complete with answers will be unlimited!
Challenges

- SPICE utilizes power-of-ten notation for small and large values. The standard representation of this in a plain-text format is a capital letter $E$ followed by the power value. Identify any such figures in the SPICE output listing, and express them in regular decimal notation.

- Modify this SPICE netlist to utilize a voltage source with a value of 16 Volts instead of 7 Volts.

- Modify this SPICE netlist to specify resistor $R_1$’s resistance using scientific (power-of-ten) notation.

- Modify this SPICE netlist to specify resistor $R_1$’s resistance using metric prefix (“kilo”) notation.

- Explain why $i(v_1)$ registers as a negative value while both $i(v_{amm1})$ and $i(v_{amm2})$ register as positive values.

- Apply Kirchhoff’s Current Law to current values in this circuit.
5.3 Diagnostic reasoning

These questions are designed to stimulate your deductive and inductive thinking, where you must apply general principles to specific scenarios (deductive) and also derive conclusions about the failed circuit from specific details (inductive). In a Socratic discussion with your instructor, the goal is for these questions to reinforce your recall and use of general circuit principles and also challenge your ability to integrate multiple symptoms into a sensible explanation of what’s wrong in a circuit. Your instructor may also pose additional questions based on those assigned, in order to further challenge and sharpen your diagnostic abilities.

As always, your goal is to fully explain your analysis of each problem. Simply obtaining a correct answer is not good enough – you must also demonstrate sound reasoning in order to successfully complete the assignment. Your instructor’s responsibility is to probe and challenge your understanding of the relevant principles and analytical processes in order to ensure you have a strong foundation upon which to build further understanding.

You will note a conspicuous lack of answers given for these diagnostic questions. Unlike standard textbooks where answers to every other question are given somewhere toward the back of the book, here in these learning modules students must rely on other means to check their work. The best way by far is to debate the answers with fellow students and also with the instructor during the Socratic dialogue sessions intended to be used with these learning modules. Reasoning through challenging questions with other people is an excellent tool for developing strong reasoning skills.

Another means of checking your diagnostic answers, where applicable, is to use circuit simulation software to explore the effects of faults placed in circuits. For example, if one of these diagnostic questions requires that you predict the effect of an open or a short in a circuit, you may check the validity of your work by simulating that same fault (substituting a very high resistance in place of that component for an open, and substituting a very low resistance for a short) within software and seeing if the results agree.
5.3.1 Fault in a solderless breadboard circuit

A student built this resistor circuit on a solderless breadboard, but made a mistake positioning resistor $R_3$. It should be located one hole to the left instead of where it is right now:

Determine the amount of voltage dropped across each resistor in this faulty circuit configuration, assuming the battery outputs 9 Volts:

- $R_1 = 2 \, k\Omega$ \hspace{1cm} $V_{R1} =$
- $R_2 = 1 \, k\Omega$ \hspace{1cm} $V_{R2} =$
- $R_3 = 3.3 \, k\Omega$ \hspace{1cm} $V_{R3} =$
- $R_4 = 4.7 \, k\Omega$ \hspace{1cm} $V_{R4} =$
- $R_5 = 4.7 \, k\Omega$ \hspace{1cm} $V_{R5} =$

Suppose the student realizes there is a mistake, and in an attempt to correct the mistake decides to move the battery’s positive (+) wire one hole to the right on the breadboard in order to align with resistor $R_3$. If this is the only change made to the circuit, what will be the result?

5.3.2 Faults in a printed circuit

Predict the effects of the following faults in this circuit, one fault at a time, assuming the power supply is a fixed-voltage unit:

- If $R_1$ fails open . . .
- If $R_2$ fails open . . .
- If $R_3$ fails open . . .
- If $R_4$ fails open . . .
- If $R_1$ fails shorted . . .
- If $R_2$ fails shorted . . .
- If $R_3$ fails shorted . . .
- If $R_4$ fails shorted . . .

**Challenges**

- Components soldered to circuit boards cannot be easily removed, as de-soldering is required. This makes it difficult to test for current through any component, as there is no convenient way to break the circuit so as to insert an ammeter. Describe how it may be possible to infer current through certain circuit board components using only a voltmeter.
5.3.3 Faulty electric lamp array

Something has failed in this array of electric lamps, because only the middle and bottom strings are illuminating. None of the lamps in the upper string emit any light. A technician takes a voltage measurement (as shown):

Identify at least two individual faults, either one independently capable of accounting for the symptoms of this circuit.

Challenges

- Suppose the voltmeter registered 36 Volts instead of 0 Volts in this failed circuit. Identify at least two independent faults which could explain all symptoms.

- Suppose nothing was failed in this circuit. How much voltage should the voltmeter register when connected as shown?

- Suppose nothing was failed in this circuit. What would happen if the DMM were connected to the circuit in the same place, but configured to be an ammeter rather than a voltmeter?
Chapter 6

Projects and Experiments

The following project and experiment descriptions outline things you can build to help you understand circuits. With any real-world project or experiment there exists the potential for physical harm. *Electricity can be very dangerous in certain circumstances, and you should follow proper safety precautions at all times!*

6.1 Recommended practices

This section outlines some recommended practices for all circuits you design and construct.
6.1.1 Safety first!

Electricity, when passed through the human body, causes uncomfortable sensations and in large enough measures\(^1\) will cause muscles to involuntarily contract. The overriding of your nervous system by the passage of electrical current through your body is particularly dangerous in regard to your heart, which is a vital muscle. Very large amounts of current can produce serious internal burns in addition to all the other effects.

Cardio-pulmonary resuscitation (CPR) is the standard first-aid for any victim of electrical shock. This is a very good skill to acquire if you intend to work with others on dangerous electrical circuits. You should never perform tests or work on such circuits unless someone else is present who is proficient in CPR.

As a general rule, any voltage in excess of 30 Volts poses a definitive electric shock hazard, because beyond this level human skin does not have enough resistance to safely limit current through the body. “Live” work of any kind with circuits over 30 volts should be avoided, and if unavoidable should only be done using electrically insulated tools and other protective equipment (e.g. insulating shoes and gloves). If you are unsure of the hazards, or feel unsafe at any time, stop all work and distance yourself from the circuit!

A policy I strongly recommend for students learning about electricity is to never come into electrical contact\(^2\) with an energized conductor, no matter what the circuit’s voltage\(^3\) level! Enforcing this policy may seem ridiculous when the circuit in question is powered by a single battery smaller than the palm of your hand, but it is precisely this instilled habit which will save a person from bodily harm when working with more dangerous circuits. Experience has taught me that students who learn early on to be careless with safe circuits have a tendency to be careless later with dangerous circuits!

In addition to the electrical hazards of shock and burns, the construction of projects and running of experiments often poses other hazards such as working with hand and power tools, potential

---

\(^1\)Professor Charles Dalziel published a research paper in 1961 called “The Deleterious Effects of Electric Shock” detailing the results of electric shock experiments with both human and animal subjects. The threshold of perception for human subjects holding a conductor in their hand was in the range of 1 milliampere of current (less than this for alternating current, and generally less for female subjects than for male). Loss of muscular control was exhibited by half of Dalziel’s subjects at less than 10 milliamperes alternating current. Extreme pain, difficulty breathing, and loss of all muscular control occurred for over 99% of his subjects at direct currents less than 100 milliamperes and alternating currents less than 30 milliamperes. In summary, it doesn’t require much electric current to induce painful and even life-threatening effects in the human body! Your first and best protection against electric shock is maintaining an insulating barrier between your body and the circuit in question, such that current from that circuit will be unable to flow through your body.

\(^2\)By “electrical contact” I mean either directly touching an energized conductor with any part of your body, or indirectly touching it through a conductive tool. The only physical contact you should ever make with an energized conductor is via an electrically insulated tool, for example a screwdriver with an electrically insulated handle, or an insulated test probe for some instrument.

\(^3\)Another reason for consistently enforcing this policy, even on low-voltage circuits, is due to the dangers that even some low-voltage circuits harbor. A single 12 Volt automobile battery, for example, can cause a surprising amount of damage if short-circuited simply due to the high current levels (i.e. very low internal resistance) it is capable of, even though the voltage level is too low to cause a shock through the skin. Mechanics wearing metal rings, for example, are at risk from severe burns if their rings happen to short-circuit such a battery! Furthermore, even when working on circuits that are simply too low-power (low voltage and low current) to cause any bodily harm, touching them while energized can pose a threat to the circuit components themselves. In summary, it generally wise (and always a good habit to build) to “power down” any circuit before making contact between it and your body.
contact with high temperatures, potential chemical exposure, etc. You should never proceed with a project or experiment if you are unaware of proper tool use or lack basic protective measures (e.g. personal protective equipment such as safety glasses) against such hazards.

Some other safety-related practices should be followed as well:

- All power conductors extending outward from the project must be firmly strain-relieved (e.g. “cord grips” used on line power cords), so that an accidental tug or drop will not compromise circuit integrity.

- All electrical connections must be sound and appropriately made (e.g. soldered wire joints rather than twisted-and-taped; terminal blocks rather than solderless breadboards for high-current or high-voltage circuits). Use “touch-safe” terminal connections with recessed metal parts to minimize risk of accidental contact.

- Always provide overcurrent protection in any circuit you build. Always. This may be in the form of a fuse, a circuit breaker, and/or an electronically current-limited power supply.

- Always ensure circuit conductors are rated for more current than the overcurrent protection limit. Always. A fuse does no good if the wire or printed circuit board trace will “blow” before it does!

- Always bond metal enclosures to Earth ground for any line-powered circuit. Always. Ensuring an equipotential state between the enclosure and Earth by making the enclosure electrically common with Earth ground ensures no electric shock can occur simply by one’s body bridging between the Earth and the enclosure.

- Avoid building a high-energy circuit when a low-energy circuit will suffice. For example, I always recommend beginning students power their first DC resistor circuits using small batteries rather than with line-powered DC power supplies. The intrinsic energy limitations of a dry-cell battery make accidents highly unlikely.

- Use line power receptacles that are GFCI (Ground Fault Current Interrupting) to help avoid electric shock from making accidental contact with a “hot” line conductor.

- Always wear eye protection when working with tools or live systems having the potential to eject material into the air. Examples of such activities include soldering, drilling, grinding, cutting, wire stripping, working on or near energized circuits, etc.

- Always use a step-stool or stepladder to reach high places. Never stand on something not designed to support a human load.

- When in doubt, ask an expert. If anything even seems remotely unsafe to you, do not proceed without consulting a trusted person fully knowledgeable in electrical safety.
6.1.2 Other helpful tips

Experience has shown the following practices to be very helpful, especially when students make their own component selections, to ensure the circuits will be well-behaved:

- Avoid resistor values less than 1 kΩ or greater than 100 kΩ, unless such values are definitely necessary\(^4\). Resistances below 1 kΩ may draw excessive current if directly connected to a voltage source of significant magnitude, and may also complicate the task of accurately measuring current since any ammeter’s non-zero resistance inserted in series with a low-value circuit resistor will significantly alter the total resistance and thereby skew the measurement. Resistances above 100 kΩ may complicate the task of measuring voltage since any voltmeter’s finite resistance connected in parallel with a high-value circuit resistor will significantly alter the total resistance and thereby skew the measurement. Similarly, AC circuit impedance values should be between 1 kΩ and 100 kΩ, and for all the same reasons.

- Ensure all electrical connections are low-resistance and physically rugged. For this reason, one should avoid compression splices (e.g. “butt” connectors), solderless breadboards\(^5\), and wires that are simply twisted together.

- Build your circuit with testing in mind. For example, provide convenient connection points for test equipment (e.g. multimeters, oscilloscopes, signal generators, logic probes).

- Design permanent projects with maintenance in mind. The more convenient you make maintenance tasks, the more likely they will get done.

- **Always document and save your work.** Circuits lacking schematic diagrams are more difficult to troubleshoot than documented circuits. Similarly, circuit construction is simpler when a schematic diagram precedes construction. Experimental results are easier to interpret when comprehensively recorded. Consider modern videorecording technology for this purpose where appropriate.

- Record your steps when troubleshooting. **Talk to yourself** when solving problems. These simple steps clarify thought and simplify identification of errors.

---

\(^4\)An example of a necessary resistor value much less than 1 kΩ is a shunt resistor used to produce a small voltage drop for the purpose of sensing current in a circuit. Such shunt resistors must be low-value in order not to impose an undue load on the rest of the circuit. An example of a necessary resistor value much greater than 100 kΩ is an electrostatic drain resistor used to dissipate stored electric charges from body capacitance for the sake of preventing damage to sensitive semiconductor components, while also preventing a path for current that could be dangerous to the person (i.e. shock).

\(^5\)Admittedly, solderless breadboards are very useful for constructing complex electronic circuits with many components, especially DIP-style integrated circuits (ICs), but they tend to give trouble with connection integrity after frequent use. An alternative for projects using low counts of ICs is to solder IC sockets into prototype printed circuit boards (PCBs) and run wires from the soldered pins of the IC sockets to terminal blocks where reliable temporary connections may be made.
6.1.3 Terminal blocks for circuit construction

Terminal blocks are the standard means for making electric circuit connections in industrial systems. They are also quite useful as a learning tool, and so I highly recommend their use in lieu of solderless breadboards\(^6\). Terminal blocks provide highly reliable connections capable of withstanding significant voltage and current magnitudes, and they force the builder to think very carefully about component layout which is an important mental practice. Terminal blocks that mount on standard 35 mm DIN rail\(^7\) are made in a wide range of types and sizes, some with built-in disconnection switches, some with built-in components such as rectifying diodes and fuseholders, all of which facilitate practical circuit construction.

I recommend every student of electricity build their own terminal block array for use in constructing experimental circuits, consisting of several terminal blocks where each block has at least 4 connection points all electrically common to each other\(^8\) and at least one terminal block that is a fuse holder for overcurrent protection. A pair of anchoring blocks hold all terminal blocks securely on the DIN rail, preventing them from sliding off the rail. Each of the terminals should bear a number, starting from 0. An example is shown in the following photograph and illustration:

Screwless terminal blocks (using internal spring clips to clamp wire and component lead ends) are preferred over screw-based terminal blocks, as they reduce assembly and disassembly time, and also minimize repetitive wrist stress from twisting screwdrivers. Some screwless terminal blocks require the use of a special tool to release the spring clip, while others provide buttons\(^9\) for this task which may be pressed using the tip of any suitable tool.

\(^6\)Solderless breadboards are preferable for complicated electronic circuits with multiple integrated “chip” components, but for simpler circuits I find terminal blocks much more practical. An alternative to solderless breadboards for “chip” circuits is to solder chip sockets onto a PCB and then use wires to connect the socket pins to terminal blocks. This also accommodates surface-mount components, which solderless breadboards do not.
\(^7\)DIN rail is a metal rail designed to serve as a mounting point for a wide range of electrical and electronic devices such as terminal blocks, fuses, circuit breakers, relay sockets, power supplies, data acquisition hardware, etc.
\(^8\)Sometimes referred to as equipotential, same-potential, or potential distribution terminal blocks.
\(^9\)The small orange-colored squares seen in the above photograph are buttons for this purpose, and may be actuated by pressing with any tool of suitable size.
The following example shows how such a terminal block array might be used to construct a series-parallel resistor circuit consisting of four resistors and a battery:

![Pictorial diagram](image)

Numbering on the terminal blocks provides a very natural translation to SPICE\textsuperscript{10} netlists, where component connections are identified by terminal number:

\texttt{v1 1 0 dc 6}
\texttt{r1 2 5 7100}
\texttt{r2 5 8 2200}
\texttt{r3 2 8 3300}
\texttt{r4 8 11 4700}
\texttt{rjmp1 1 2 0.01}
\texttt{rjmp2 0 11 0.01}
\texttt{.op}
\texttt{.end}

Note the use of “jumper” resistances \texttt{rjmp1} and \texttt{rjmp2} to describe the wire connections between terminals 1 and 2 and between terminals 0 and 11, respectively. Being resistances, SPICE requires a resistance value for each, and here we see they have both been set to an arbitrarily low value of 0.01 Ohm realistic for short pieces of wire.

Listing all components and wires along with their numbered terminals happens to be a useful documentation method for any circuit built on terminal blocks, independent of SPICE. Such a “wiring sequence” may be thought of as a non-graphical description of an electric circuit, and is exceptionally easy to follow.

\textsuperscript{10}SPICE is computer software designed to analyze electrical and electronic circuits. Circuits are described for the computer in the form of netlists which are text files listing each component type, connection node numbers, and component values.
An example of a more elaborate terminal block array is shown in the following photograph, with terminal blocks and “ice-cube” style electromechanical relays mounted to DIN rail, which is turn mounted to a perforated subpanel. This “terminal block board” hosts an array of thirty five undedicated terminal block sections, four SPDT toggle switches, four DPDT “ice-cube” relays, a step-down control power transformer, bridge rectifier and filtering capacitor, and several fuses for overcurrent protection:

Four plastic-bottomed “feet” support the subpanel above the benchtop surface, and an unused section of DIN rail stands ready to accept other components. Safety features include electrical bonding of the AC line power cord’s ground to the metal subpanel (and all metal DIN rails), mechanical strain relief for the power cord to isolate any cord tension from wire connections, clear plastic finger guards covering the transformer’s screw terminals, as well as fused overcurrent protection for the 120 Volt AC line power and the transformer’s 12 Volt AC output. The perforated holes happen to be on \( \frac{\text{1}}{\text{4}} \text{ inch} \) centers, their presence making it very easy to attach other sections of DIN rail, or specialized electrical components, directly to the grounded metal subpanel. Such a “terminal block board” is an inexpensive yet highly flexible means to construct physically robust circuits using industrial wiring practices.

---

11 An electrical \textit{subpanel} is a thin metal plate intended for mounting inside an electrical enclosure. Components are attached to the subpanel, and the subpanel in turn bolts inside the enclosure. Subpanels allow circuit construction outside the confines of the enclosure, which speeds assembly. In this particular usage there is no enclosure, as the subpanel is intended to be used as an open platform for the convenient construction of circuits on a benchtop by students. In essence, this is a modern version of the traditional \textit{breadboard} which was literally a wooden board such as might be used for cutting loaves of bread, but which early electrical and electronic hobbyists used as platforms for the construction of circuits.

12 At the time of this writing (2019) the cost to build this board is approximately $250 US dollars.
6.1.4 Conducting experiments

An experiment is an exploratory act, a test performed for the purpose of assessing some proposition or principle. Experiments are the foundation of the scientific method, a process by which careful observation helps guard against errors of speculation. All good experiments begin with an hypothesis, defined by the American Heritage Dictionary of the English Language as:

An assertion subject to verification or proof, as (a) A proposition stated as a basis for argument or reasoning. (b) A premise from which a conclusion is drawn. (c) A conjecture that accounts, within a theory or ideational framework, for a set of facts and that can be used as a basis for further investigation.

Stated plainly, an hypothesis is an educated guess about cause and effect. The correctness of this initial guess matters little, because any well-designed experiment will reveal the truth of the matter. In fact, incorrect hypotheses are often the most valuable because the experiments they engender lead us to surprising discoveries. One of the beautiful aspects of science is that it is more focused on the process of learning than about the status of being correct\(^{13}\). In order for an hypothesis to be valid, it must be testable\(^{14}\), which means it must be a claim possible to refute given the right data. Hypotheses impossible to critique are useless.

Once an hypothesis has been formulated, an experiment must be designed to test that hypothesis. A well-designed experiment requires careful regulation of all relevant variables, both for personal safety and for prompting the hypothesized results. If the effects of one particular variable are to be tested, the experiment must be run multiple times with different values of (only) that particular variable. The experiment set up with the “baseline” variable set is called the control, while the experiment set up with different value(s) is called the test or experimental.

For some hypotheses a viable alternative to a physical experiment is a computer-simulated experiment or even a thought experiment. Simulations performed on a computer test the hypothesis against the physical laws encoded within the computer simulation software, and are particularly useful for students learning new principles for which simulation software is readily available\(^{15}\).

\(^{13}\)Science is more about clarifying our view of the universe through a systematic process of error detection than it is about proving oneself to be right. Some scientists may happen to have large egos – and this may have more to do with the ways in which large-scale scientific research is funded than anything else – but scientific method itself is devoid of ego, and if embraced as a practical philosophy is quite an effective stimulant for humility. Within the education system, scientific method is particularly valuable for helping students break free of the crippling fear of being wrong. So much emphasis is placed in formal education on assessing correct retention of facts that many students are fearful of saying or doing anything that might be perceived as a mistake, and of course making mistakes (i.e. having one’s hypotheses disproven by experiment) is an indispensable tool for learning. Introducing science in the classroom – real science characterized by individuals forming actual hypotheses and testing those hypotheses by experiment – helps students become self-directed learners.

\(^{14}\)This is the principle of falsifiability: that a scientific statement has value only insofar as it is liable to disproof given the requisite experimental evidence. Any claim that is un falsifiable – that is, a claim which can never be disproven by any evidence whatsoever – could be completely wrong and we could never know it.

\(^{15}\)A very pertinent example of this is learning how to analyze electric circuits using simulation software such as SPICE. A typical experimental cycle would proceed as follows: (1) Find or invent a circuit to analyze; (2) Apply your analytical knowledge to that circuit, predicting all voltages, currents, powers, etc. relevant to the concepts you are striving to master; (3) Run a simulation on that circuit, collecting “data” from the computer when complete; (4) Evaluate whether or not your analyses (i.e. predicted voltages, currents, etc.) agree with the computer-generated results; (5) If so, your analyses are (provisionally) correct – if not, examine your analyses and the computer simulation again to determine the source of error; (6) Repeat this process as many times as necessary until you achieve mastery.
6.1. RECOMMENDED PRACTICES

Thought experiments are useful for detecting inconsistencies within your own understanding of some subject, rather than testing your understanding against physical reality.

Here are some general guidelines for conducting experiments:

- The clearer and more specific the hypothesis, the better. Vague or unfalsifiable hypotheses are useless because they will fit any experimental results, and therefore the experiment cannot teach you anything about the hypothesis.

- Collect as much data (i.e. information, measurements, sensory experiences) generated by an experiment as is practical. This includes the time and date of the experiment, too!

- *Never* discard or modify data gathered from an experiment. If you have reason to believe the data is unreliable, write notes to that effect, but never throw away data just because you think it is untrustworthy. It is quite possible that even “bad” data holds useful information, and that someone else may be able to uncover its value even if you do not.

- Prioritize *quantitative* data over *qualitative* data wherever practical. Quantitative data is more specific than qualitative, less prone to subjective interpretation on the part of the experimenter, and amenable to an arsenal of analytical methods (e.g. statistics).

- Guard against your own bias(es) by making your experimental results available to others. This allows other people to scrutinize your experimental design and collected data, for the purpose of detecting and correcting errors you may have missed. Document your experiment such that others may independently replicate it.

- Always be looking for sources of error. No physical measurement is perfect, and so it is impossible to achieve *exact* values for any variable. Quantify the amount of uncertainty (i.e. the “tolerance” of errors) whenever possible, and be sure your hypothesis does not depend on precision better than this!

- Always remember that scientific confirmation is provisional – no number of “successful” experiments will prove an hypothesis true for all time, but a single experiment can disprove it. Put into simpler terms, *truth is elusive but error is within reach*.

- Remember that scientific method is about *learning*, first and foremost. An unfortunate consequence of scientific triumph in modern society is that science is often viewed by non-practitioners as an unerring source of truth, when in fact science is an ongoing process of challenging existing ideas to probe for errors and oversights. This is why it is perfectly acceptable to have a failed hypothesis, and why the only truly failed experiment is one where nothing was learned.
The following is an example of a well-planned and executed experiment, in this case a physical experiment demonstrating Ohm's Law.

**Planning Time/Date = 09:30 on 12 February 2019**

**HYPOTHESIS:** the current through any resistor should be exactly proportional to the voltage impressed across it.

**PROCEDURE:** connect a resistor rated 1 k Ohm and 1/4 Watt to a variable-voltage DC power supply. Use an ammeter in series to measure resistor current and a voltmeter in parallel to measure resistor voltage.

**RISKS AND MITIGATION:** excessive power dissipation may harm the resistor and/or pose a burn hazard, while excessive voltage poses an electric shock hazard. 30 Volts is a safe maximum voltage for laboratory practices, and according to Joule’s Law a 1000 Ohm resistor will dissipate 0.25 Watts at 15.81 Volts ($P = V^2 / R$), so I will remain below 15 Volts just to be safe.

**Analysis Time/Date = 10:57 on 12 February 2019**

**ANALYSIS:** current definitely increases with voltage, and although I expected exactly one milliAmpere per Volt the actual current was usually less than that. The voltage/current ratios ranged from a low of 1036.87 (at 8.1 Volts) to a high of 1037.81 (at 14 Volts), but this represents a variance of only -0.0365% to +0.0541% from the average, indicating a very consistent proportionality -- results consistent with Ohm’s Law.

**ERROR SOURCES:** one major source of error is the resistor’s value itself. I did not measure it, but simply assumed color bands of brown-black-red meant exactly 1000 Ohms. Based on the data I think the true resistance is closer to 1037 Ohms. Another possible explanation is multimeter calibration error. However, neither explains the small positive and negative variances from the average. This might be due to electrical noise, a good test being to repeat the same experiment to see if the variances are the same or different. Noise should generate slightly different results every time.

Analysis Time/Date = 13:06 on 14 February 2019

ANALYSIS: perfect agreement between data and hypothesis -- current is precisely 1/1000 of the applied voltage for all values. Anything other than perfect agreement would have probably meant my netlist was incorrect. The negative current values surprised me, but it seems this is just how SPICE interprets normal current through a DC voltage source.

ERROR SOURCES: none.
As gratuitous as it may seem to perform experiments on a physical law as well-established as Ohm’s Law, even the examples listed previously demonstrate opportunity for real learning. In the physical experiment example, the student should identify and explain why their data does not perfectly agree with the hypothesis, and this leads them naturally to consider sources of error. In the computer-simulated experiment, the student is struck by SPICE’s convention of denoting regular current through a DC voltage source as being negative in sign, and this is also useful knowledge for future simulations. Scientific experiments are most interesting when things do not go as planned!

Aside from verifying well-established physical laws, simple experiments are extremely useful as educational tools for a wide range of purposes, including:

- Component familiarization (e.g. Which terminals of this switch connect to the NO versus NC contacts?)
- System testing (e.g. How heavy of a load can my AC-DC power supply source before the semiconductor components reach their thermal limits?)
- Learning programming languages (e.g. Let’s try to set up an “up” counter function in this PLC!)

Above all, the priority here is to inculcate the habit of hypothesizing, running experiments, and analyzing the results. This experimental cycle not only serves as an excellent method for self-directed learning, but it also works exceptionally well for troubleshooting faults in complex systems, and for these reasons should be a part of every technician’s and every engineer’s education.

### 6.1.5 Constructing projects

Designing, constructing, and testing projects is a very effective means of practical education. Within a formal educational setting, projects are generally chosen (or at least vetted) by an instructor to ensure they may be reasonably completed within the allotted time of a course or program of study, and that they sufficiently challenge the student to learn certain important principles. In a self-directed environment, projects are just as useful as a learning tool but there is some risk of unwittingly choosing a project beyond one’s abilities, which can lead to frustration.

Here are some general guidelines for managing projects:

- Define your goal(s) before beginning a project: what do you wish to achieve in building it? What, exactly, should the completed project do?
- Analyze your project prior to construction. Document it in appropriate forms (e.g. schematic diagrams), predict its functionality, anticipate all associated risks. In other words, plan ahead.
- Set a reasonable budget for your project, and stay within it.
- Identify any deadlines, and set reasonable goals to meet those deadlines.
- Beware of scope creep: the tendency to modify the project’s goals before it is complete.
- Document your progress! An easy way to do this is to use photography or videography: take photos and/or videos of your project as it progresses. Document failures as well as successes, because both are equally valuable from the perspective of learning.
6.2 Experiment: voltmeter resistance

Ideal voltmeters possess infinite resistance, so as to draw zero current (and therefore pose no energy burden) when connected to a circuit. Real voltmeters fall short of this ideal goal. Your task is to set up an experiment whereby you determine the actual resistance of a voltmeter under realistic operating conditions.

One way to do this is to build a circuit with a known output voltage predicted in advance, and then measure that output voltage with a voltmeter to see how closely the voltmeter’s measurement agrees with the predicted (ideal) voltage. This circuit should be built in such a way that the loading effect of the voltmeter will be clearly evident.

A simple circuit fitting this requirement is a 2:1 ratio voltage divider, constructed of two identical-valued resistors connected in series, powered by a regulated voltage source (e.g. laboratory-style power supply). The resistor values should be rather large, in order that the paralleled resistance of the voltmeter makes a significant different to the division ratio of the circuit:

\[ \text{V}_{\text{supply}} \] (regulated) \hspace{1cm} R \hspace{1cm} R \hspace{1cm} \text{Voltmeter} \hspace{1cm} \text{V}_{\text{out}} \]

The power supply’s output voltage may be measured by a voltmeter with little or no loading effect, because regulated power supplies have very little internal resistance and so will not be appreciably affected by the miniscule current drawn by a directly-connected voltmeter. The loading effect on the voltage divider’s output (\(V_{\text{out}}\)), however, will be much more pronounced because the voltmeter’s current must pass through the upper resistor of the divider which has been chosen to be fairly large in value.

First and foremost, identify any potential hazards posed by this experiment. If any exist, identify how to mitigate each of those risks to ensure personal safety as well as ensure no components or equipment will be damaged.

Choose two resistors of equal value, chosen such that the meter’s loading effect will be noticeable. It is up to you to select two resistors which are as close in value to each other as possible, and also to demonstrate the means by which you have determined their equality. Document the resistance values.

Next, use your DMM to measure the power supply’s voltage. Document this value as well.

Calculate the voltage divider’s output voltage (\(V_{\text{out}}\)) with no meter connected. Document this “ideal” voltage value.
Connect your DMM (set to measure voltage) and measure the voltage divider’s output voltage ($V_{out}$). Compare this measured voltage value with the predicted voltage value from the previous step.

Calculate the voltmeter’s internal resistance based on the discrepancy between these two voltages: $V_{out}$ (ideal) versus $V_{out}$ (empirical). Be sure to explain your reasoning at every step in the process.

Be sure to document all data in a neat and well-organized format, easily understood by anyone viewing it. Be prepared to explain your reasoning at every step, and also to demonstrate the safe and proper use of all materials, components, and equipment. If a live demonstration is not practical, record your actions on video.

**Challenges**

- An alternative to using a voltage divider is to simply measure the power supply’s voltage through a high-valued resistor (i.e. connecting a resistor in series with one of the voltmeter test leads). Explain how this experiment could work as well.
- Predict the effect of the upper resistor failing open.
- Predict the effect of the upper resistor failing shorted.
- Predict the effect of the lower resistor failing open.
- Predict the effect of the lower resistor failing shorted.
6.3 Experiment: SPICE modeling of a series-parallel circuit

SPICE is a powerful computer-based simulation tool for circuit analysis, and if mastered provides a way for students to create their own practice problems. In this experiment, we will do just that: create a series-parallel resistor circuit practice problem, and use SPICE to give us the answer key!

Your hypothesis may simply be the predicted values for voltage and/or current in any series-parallel resistor circuit of your choosing. Feel free to take any series-parallel circuit found in this learning module – especially one with an accompanying SPICE netlist – modify it, and use this as the basis of your experiment. The *SPICE Modeling of Resistor Circuits* learning module is another resource for example circuits and SPICE netlists, which you may sample and modify.

**EXPERIMENT CHECKLIST:**

- **Prior to experimentation:**
  - √ Write an hypothesis (i.e. a detailed description of what you expect will happen) unambiguous enough that it could be disproven given the right data.
  - √ Write a procedure to test the hypothesis, complete with adequate controls and documentation (e.g. schematic diagrams, programming code).
  - √ Identify any risks (e.g. shock hazard, component damage) and write a mitigation plan based on best practices and component ratings.

- **During experimentation:**
  - √ Safe practices followed at all times (e.g. no contact with energized circuit).
  - √ Correct equipment usage according to manufacturer’s recommendations.
  - √ All data collected, ideally quantitative with full precision (i.e. no rounding).

- **After each experimental run:**
  - √ If the results fail to match the hypothesis, identify the error(s), correct the hypothesis and/or revise the procedure, and re-run the experiment.
  - √ Identify any uncontrolled sources of error in the experiment.

- **After all experimental re-runs:**
  - √ Save all data for future reference.
  - √ Write an analysis of experimental results and lessons learned.

**Challenges**

- Science is an *iterative* process, and for this reason is never complete. Following the results of your experiment, what would you propose for your *next* hypothesis and *next* experimental
procedure? Hint: if your experiment produced any unexpected results, exploring those unexpected results is often a very good basis for the next experiment!

- How can you alter the value of a resistor in a SPICE netlist?
- How can you reverse the polarity of a voltage or current source in a SPICE netlist?
6.4 Experiment: demonstrate KVL in a series-parallel circuit

Kirchhoff’s Voltage Law (KVL) is a fundamental principle of electric circuits and must be well-understood in order to analyze circuit networks and diagnose circuit faults. Your task is to devise and execute an experiment to demonstrate the validity of Kirchhoff’s Voltage Law within a series-parallel DC resistor circuit of your choice.

In order to make this demonstration of KVL thorough, you should run multiple tests. In other words, choose multiple “loops” (or “paths”) within your circuit, and prove that KVL is true in every instance.

**EXPERIMENT CHECKLIST:**

- **Prior to experimentation:**
  - √ Write an hypothesis (i.e. a detailed description of what you expect will happen) unambiguous enough that it could be disproven given the right data.

6.5 Experiment: demonstrate KCL in a series-parallel circuit

Kirchhoff’s Current Law (KCL) is a fundamental principle of electric circuits and must be well-understood in order to analyze circuit networks and diagnose circuit faults. Your task is to devise and execute an experiment to demonstrate the validity of Kirchhoff’s Current Law within a series-parallel DC resistor circuit of your choice.

In order to make this demonstration of KCL thorough, you should run multiple tests. In other words, choose multiple nodes within your circuit, and prove that KCL is true in every instance.

Problem-Solving Strategies

The ability to solve complex problems is arguably one of the most valuable skills one can possess, and this skill is particularly important in any science-based discipline.

- **Study principles, not procedures.** Don’t be satisfied with merely knowing how to compute solutions – learn *why* those solutions work.

- **Identify** what it is you need to solve, identify all relevant data, identify all units of measurement, identify any general principles or formulae linking the given information to the solution, and then identify any “missing pieces” to a solution. **Annotate** all diagrams with this data.

- **Sketch a diagram** to help visualize the problem. When building a real system, always devise a plan for that system and analyze its function *before* constructing it.

- **Follow the units of measurement and meaning of every calculation.** If you are ever performing mathematical calculations as part of a problem-solving procedure, and you find yourself unable to apply each and every intermediate result to some aspect of the problem, it means you don’t understand what you are doing. Properly done, every mathematical result should have practical meaning for the problem, and not just be an abstract number. You should be able to identify the proper units of measurement for each and every calculated result, and show where that result fits into the problem.

- **Perform “thought experiments”** to explore the effects of different conditions for theoretical problems. When troubleshooting real systems, perform *diagnostic tests* rather than visually inspecting for faults, the best diagnostic test being the one giving you the most information about the nature and/or location of the fault with the fewest steps.

- **Simplify the problem** until the solution becomes obvious, and then use that obvious case as a model to follow in solving the more complex version of the problem.

- **Check for exceptions** to see if your solution is incorrect or incomplete. A good solution will work for *all* known conditions and criteria. A good example of this is the process of testing scientific hypotheses: the task of a scientist is not to find support for a new idea, but rather to *challenge* that new idea to see if it holds up under a battery of tests. The philosophical
principle of *reductio ad absurdum* (i.e. disproving a general idea by finding a specific case where it fails) is useful here.

- **Work “backward”** from a hypothetical solution to a new set of given conditions.
- **Add quantities** to problems that are qualitative in nature, because sometimes a little math helps illuminate the scenario.
- **Sketch graphs** illustrating how variables relate to each other. These may be quantitative (i.e. with realistic number values) or qualitative (i.e. simply showing increases and decreases).
- **Treat quantitative problems as qualitative** in order to discern the relative magnitudes and/or directions of change of the relevant variables. For example, try determining what happens if a certain variable were to increase or decrease before attempting to precisely calculate quantities: how will each of the dependent variables respond, by increasing, decreasing, or remaining the same as before?
- **Consider limiting cases.** This works especially well for qualitative problems where you need to determine which direction a variable will change. Take the given condition and magnify that condition to an extreme degree as a way of simplifying the direction of the system’s response.
- **Check your work.** This means regularly testing your conclusions to see if they make sense. This does *not* mean repeating the same steps originally used to obtain the conclusion(s), but rather to use some other means to check validity. Simply repeating procedures often leads to *repeating the same errors* if any were made, which is why alternative paths are better.

Instructional philosophy

“The unexamined circuit is not worth energizing” – Socrates (if he had taught electricity)

These learning modules, although useful for self-study, were designed to be used in a formal learning environment where a subject-matter expert challenges students to digest the content and exercise their critical thinking abilities in the answering of questions and in the construction and testing of working circuits.

The following principles inform the instructional and assessment philosophies embodied in these learning modules:

• The first goal of education is to enhance clear and independent thought, in order that every student reach their fullest potential in a highly complex and inter-dependent world. Robust reasoning is always more important than particulars of any subject matter, because its application is universal.

• Literacy is fundamental to independent learning and thought because text continues to be the most efficient way to communicate complex ideas over space and time. Those who cannot read with ease are limited in their ability to acquire knowledge and perspective.

• Articulate communication is fundamental to work that is complex and interdisciplinary.

• Faulty assumptions and poor reasoning are best corrected through challenge, not presentation. The rhetorical technique of *reductio ad absurdum* (disproving an assertion by exposing an absurdity) works well to discipline student’s minds, not only to correct the problem at hand but also to learn how to detect and correct future errors.

• Important principles should be repeatedly explored and widely applied throughout a course of study, not only to reinforce their importance and help ensure their mastery, but also to showcase the interconnectedness and utility of knowledge.
These learning modules were expressly designed to be used in an “inverted” teaching environment where students first read the introductory and tutorial chapters on their own, then individually attempt to answer the questions and construct working circuits according to the experiment and project guidelines. The instructor never lectures, but instead meets regularly with each individual student to review their progress, answer questions, identify misconceptions, and challenge the student to new depths of understanding through further questioning. Regular meetings between instructor and student should resemble a Socratic dialogue, where questions serve as scalpels to dissect topics and expose assumptions. The student passes each module only after consistently demonstrating their ability to logically analyze and correctly apply all major concepts in each question or project/experiment. The instructor must be vigilant in probing each student’s understanding to ensure they are truly reasoning and not just memorizing. This is why “Challenge” points appear throughout, as prompts for students to think deeper about topics and as starting points for instructor queries. Sometimes these challenge points require additional knowledge that hasn’t been covered in the series to answer in full. This is okay, as the major purpose of the Challenges is to stimulate analysis and synthesis on the part of each student.

The instructor must possess enough mastery of the subject matter and awareness of students’ reasoning to generate their own follow-up questions to practically any student response. Even completely correct answers given by the student should be challenged by the instructor for the purpose of having students practice articulating their thoughts and defending their reasoning. Conceptual errors committed by the student should be exposed and corrected not by direct instruction, but rather by reducing the errors to an absurdity through well-chosen questions and thought experiments posed by the instructor. Becoming proficient at this style of instruction requires time and dedication, but the positive effects on critical thinking for both student and instructor are spectacular.

An inspection of these learning modules reveals certain unique characteristics. One of these is a bias toward thorough explanations in the tutorial chapters. Without a live instructor to explain concepts and applications to students, the text itself must fulfill this role. This philosophy results in lengthier explanations than what you might typically find in a textbook, each step of the reasoning process fully explained, including footnotes addressing common questions and concerns students raise while learning these concepts. Each tutorial seeks to not only explain each major concept in sufficient detail, but also to explain the logic of each concept and how each may be developed in sufficient detail, but also to explain the logic of each concept and how each may be developed.

---

1In a traditional teaching environment, students first encounter new information via lecture from an expert, and then independently apply that information via homework. In an “inverted” course of study, students first encounter new information via homework, and then independently apply that information under the scrutiny of an expert. The expert’s role in lecture is to simply explain, but the expert’s role in an inverted session is to challenge, critique, and if necessary explain where gaps in understanding still exist.

2Socrates is a figure in ancient Greek philosophy famous for his unflinching style of questioning. Although he authored no texts, he appears as a character in Plato’s many writings. The essence of Socratic philosophy is to leave no question unexamined and no point of view unchallenged. While purists may argue a topic such as electric circuits is too narrow for a true Socratic-style dialogue, I would argue that the essential thought processes involved with scientific reasoning on any topic are not far removed from the Socratic ideal, and that students of electricity and electronics would do very well to challenge assumptions, pose thought experiments, identify fallacies, and otherwise employ the arsenal of critical thinking skills modeled by Socrates.

3This rhetorical technique is known by the Latin phrase reductio ad absurdum. The concept is to expose errors by counter-example, since only one solid counter-example is necessary to disprove a universal claim. As an example of this, consider the common misconception among beginning students of electricity that voltage cannot exist without current. One way to apply reductio ad absurdum to this statement is to ask how much current passes through a fully-charged battery connected to nothing (i.e. a clear example of voltage existing without current).
from “first principles”. Again, this reflects the goal of developing clear and independent thought in students’ minds, by showing how clear and logical thought was used to forge each concept. Students benefit from witnessing a model of clear thinking in action, and these tutorials strive to be just that.

Another characteristic of these learning modules is a lack of step-by-step instructions in the Project and Experiment chapters. Unlike many modern workbooks and laboratory guides where step-by-step instructions are prescribed for each experiment, these modules take the approach that students must learn to closely read the tutorials and apply their own reasoning to identify the appropriate experimental steps. Sometimes these steps are plainly declared in the text, just not as a set of enumerated points. At other times certain steps are implied, an example being assumed competence in test equipment use where the student should not need to be told again how to use their multimeter because that was thoroughly explained in previous lessons. In some circumstances no steps are given at all, leaving the entire procedure up to the student.

This lack of prescription is not a flaw, but rather a feature. Close reading and clear thinking are foundational principles of this learning series, and in keeping with this philosophy all activities are designed to require those behaviors. Some students may find the lack of prescription frustrating, because it demands more from them than what their previous educational experiences required. This frustration should be interpreted as an unfamiliarity with autonomous thinking, a problem which must be corrected if the student is ever to become a self-directed learner and effective problem-solver. Ultimately, the need for students to read closely and think clearly is more important both in the near-term and far-term than any specific facet of the subject matter at hand. If a student takes longer than expected to complete a module because they are forced to outline, digest, and reason on their own, so be it. The future gains enjoyed by developing this mental discipline will be well worth the additional effort and delay.

Another feature of these learning modules is that they do not treat topics in isolation. Rather, important concepts are introduced early in the series, and appear repeatedly as stepping-stones toward other concepts in subsequent modules. This helps to avoid the “compartmentalization” of knowledge, demonstrating the inter-connectedness of concepts and simultaneously reinforcing them. Each module is fairly complete in itself, reserving the beginning of its tutorial to a review of foundational concepts.

This methodology of assigning text-based modules to students for digestion and then using Socratic dialogue to assess progress and hone students’ thinking was developed over a period of several years by the author with his Electronics and Instrumentation students at the two-year college level. While decidedly unconventional and sometimes even unsettling for students accustomed to a more passive lecture environment, this instructional philosophy has proven its ability to convey conceptual mastery, foster careful analysis, and enhance employability so much better than lecture that the author refuses to ever teach by lecture again.

Problems which often go undiagnosed in a lecture environment are laid bare in this “inverted” format where students must articulate and logically defend their reasoning. This, too, may be unsettling for students accustomed to lecture sessions where the instructor cannot tell for sure who comprehends and who does not, and this vulnerability necessitates sensitivity on the part of the “inverted” session instructor in order that students never feel discouraged by having their errors exposed. Everyone makes mistakes from time to time, and learning is a lifelong process! Part of the instructor’s job is to build a culture of learning among the students where errors are not seen as shameful, but rather as opportunities for progress.
To this end, instructors managing courses based on these modules should adhere to the following principles:

- Student questions are always welcome and demand thorough, honest answers. The only type of question an instructor should refuse to answer is one the student should be able to easily answer on their own. Remember, the fundamental goal of education is for each student to learn to think clearly and independently. This requires hard work on the part of the student, which no instructor should ever circumvent. Anything done to bypass the student’s responsibility to do that hard work ultimately limits that student’s potential and thereby does real harm.

- It is not only permissible, but encouraged, to answer a student’s question by asking questions in return, these follow-up questions designed to guide the student to reach a correct answer through their own reasoning.

- All student answers demand to be challenged by the instructor and/or by other students. This includes both correct and incorrect answers – the goal is to practice the articulation and defense of one’s own reasoning.

- No reading assignment is deemed complete unless and until the student demonstrates their ability to accurately summarize the major points in their own terms. Recitation of the original text is unacceptable. This is why every module contains an “Outline and reflections” question as well as a “Foundational concepts” question in the Conceptual reasoning section, to prompt reflective reading.

- No assigned question is deemed answered unless and until the student demonstrates their ability to consistently and correctly apply the concepts to variations of that question. This is why module questions typically contain multiple “Challenges” suggesting different applications of the concept(s) as well as variations on the same theme(s). Instructors are encouraged to devise as many of their own “Challenges” as they are able, in order to have a multitude of ways ready to probe students’ understanding.

- No assigned experiment or project is deemed complete unless and until the student demonstrates the task in action. If this cannot be done “live” before the instructor, video-recordings showing the demonstration are acceptable. All relevant safety precautions must be followed, all test equipment must be used correctly, and the student must be able to properly explain all results. The student must also successfully answer all Challenges presented by the instructor for that experiment or project.
Students learning from these modules would do well to abide by the following principles:

- No text should be considered fully and adequately read unless and until you can express every idea in your own words, using your own examples.

- You should always articulate your thoughts as you read the text, noting points of agreement, confusion, and epiphanies. Feel free to print the text on paper and then write your notes in the margins. Alternatively, keep a journal for your own reflections as you read. This is truly a helpful tool when digesting complicated concepts.

- Never take the easy path of highlighting or underlining important text. Instead, summarize and/or comment on the text using your own words. This actively engages your mind, allowing you to more clearly perceive points of confusion or misunderstanding on your own.

- A very helpful strategy when learning new concepts is to place yourself in the role of a teacher, if only as a mental exercise. Either explain what you have recently learned to someone else, or at least imagine yourself explaining what you have learned to someone else. The simple act of having to articulate new knowledge and skill forces you to take on a different perspective, and will help reveal weaknesses in your understanding.

- Perform each and every mathematical calculation and thought experiment shown in the text on your own, referring back to the text to see that your results agree. This may seem trivial and unnecessary, but it is critically important to ensuring you actually understand what is presented, especially when the concepts at hand are complicated and easy to misunderstand. Apply this same strategy to become proficient in the use of circuit simulation software, checking to see if your simulated results agree with the results shown in the text.

- Above all, recognize that learning is hard work, and that a certain level of frustration is unavoidable. There are times when you will struggle to grasp some of these concepts, and that struggle is a natural thing. Take heart that it will yield with persistent and varied effort, and never give up!

Students interested in using these modules for self-study will also find them beneficial, although the onus of responsibility for thoroughly reading and answering questions will of course lie with that individual alone. If a qualified instructor is not available to challenge students, a workable alternative is for students to form study groups where they challenge one another.

To high standards of education,

Tony R. Kuphaldt

---

As the old saying goes, “Insanity is trying the same thing over and over again, expecting different results.” If you find yourself stumped by something in the text, you should attempt a different approach. Alter the thought experiment, change the mathematical parameters, do whatever you can to see the problem in a slightly different light, and then the solution will often present itself more readily.

Avoid the temptation to simply share answers with study partners, as this is really counter-productive to learning. Always bear in mind that the answer to any question is far less important in the long run than the method(s) used to obtain that answer. The goal of education is to empower one’s life through the improvement of clear and independent thought, literacy, expression, and various practical skills.

Tools used

I am indebted to the developers of many open-source software applications in the creation of these learning modules. The following is a list of these applications with some commentary on each.

You will notice a theme common to many of these applications: a bias toward code. Although I am by no means an expert programmer in any computer language, I understand and appreciate the flexibility offered by code-based applications where the user (you) enters commands into a plain ASCII text file, which the software then reads and processes to create the final output. Code-based computer applications are by their very nature extensible, while WYSIWYG (What You See Is What You Get) applications are generally limited to whatever user interface the developer makes for you.

The GNU/Linux computer operating system

There is so much to be said about Linus Torvalds’ Linux and Richard Stallman’s GNU project. First, to credit just these two individuals is to fail to do justice to the mob of passionate volunteers who contributed to make this amazing software a reality. I first learned of Linux back in 1996, and have been using this operating system on my personal computers almost exclusively since then. It is free, it is completely configurable, and it permits the continued use of highly efficient Unix applications and scripting languages (e.g. shell scripts, Makefiles, sed, awk) developed over many decades. Linux not only provided me with a powerful computing platform, but its open design served to inspire my life’s work of creating open-source educational resources.

Bram Moolenaar’s Vim text editor

Writing code for any code-based computer application requires a text editor, which may be thought of as a word processor strictly limited to outputting plain-ASCII text files. Many good text editors exist, and one’s choice of text editor seems to be a deeply personal matter within the programming world. I prefer Vim because it operates very similarly to vi which is ubiquitous on Unix/Linux operating systems, and because it may be entirely operated via keyboard (i.e. no mouse required) which makes it fast to use.
Donald Knuth’s \texttt{\LaTeX} typesetting system

Developed in the late 1970’s and early 1980’s by computer scientist extraordinaire Donald Knuth to typeset his multi-volume magnum opus \textit{The Art of Computer Programming}, this software allows the production of formatted text for screen-viewing or paper printing, all by writing plain-text code to describe how the formatted text is supposed to appear. \texttt{\LaTeX} is not just a markup language for documents, but it is also a Turing-complete programming language in and of itself, allowing useful algorithms to be created to control the production of documents. Simply put, \texttt{\LaTeX} \textit{is a programmer’s approach to word processing}. Since \texttt{\LaTeX} is controlled by code written in a plain-text file, this means anyone may read that plain-text file to see exactly how the document was created. This openness afforded by the code-based nature of \texttt{\LaTeX} makes it relatively easy to learn how other people have created their own \texttt{\LaTeX} documents. By contrast, examining a beautiful document created in a conventional WYSIWYG word processor such as Microsoft \texttt{Word} suggests nothing to the reader about \textit{how} that document was created, or what the user might do to create something similar. As Mr. Knuth himself once quipped, conventional word processing applications should be called WYSIAYG (What You See Is All You Get).

Leslie Lamport’s \texttt{\LaTeX} extensions to \texttt{\LaTeX}

Like all true programming languages, \texttt{\LaTeX} is inherently extensible. So, years after the release of \texttt{\LaTeX} to the public, Leslie Lamport decided to create a massive extension allowing easier compilation of book-length documents. The result was \texttt{\LaTeXe}, which is the markup language used to create all ModEL module documents. You could say that \texttt{\LaTeX} is to \texttt{\LaTeXe} as \texttt{C} is to \texttt{C++}. This means it is permissible to use any and all \texttt{\LaTeX} commands within \texttt{\LaTeXe} source code, and it all still works. Some of the features offered by \texttt{\LaTeXe} that would be challenging to implement in \texttt{\LaTeX} include automatic index and table-of-content creation.

Tim Edwards’ \texttt{Xcircuit} drafting program

This wonderful program is what I use to create all the schematic diagrams and illustrations (but not photographic images or mathematical plots) throughout the ModEL project. It natively outputs PostScript format which is a true vector graphic format (this is why the images do not pixellate when you zoom in for a closer view), and it is so simple to use that I have never had to read the manual! Object libraries are easy to create for \texttt{Xcircuit}, being plain-text files using PostScript programming conventions. Over the years I have collected a large set of object libraries useful for drawing electrical and electronic schematics, pictorial diagrams, and other technical illustrations.
Gimp graphic image manipulation program

Essentially an open-source clone of Adobe’s PhotoShop, I use Gimp to resize, crop, and convert file formats for all of the photographic images appearing in the ModEL modules. Although Gimp does offer its own scripting language (called Script-Fu), I have never had occasion to use it. Thus, my utilization of Gimp to merely crop, resize, and convert graphic images is akin to using a sword to slice a loaf of bread.

SPICE circuit simulation program

SPICE is to circuit analysis as TeX is to document creation: it is a form of markup language designed to describe a certain object to be processed in plain-ASCII text. When the plain-text “source file” is compiled by the software, it outputs the final result. More modern circuit analysis tools certainly exist, but I prefer SPICE for the following reasons: it is free, it is fast, it is reliable, and it is a fantastic tool for teaching students of electricity and electronics how to write simple code. I happen to use rather old versions of SPICE, version 2g6 being my “go to” application when I only require text-based output. NgSPICE (version 26), which is based on Berkeley SPICE version 3f5, is used when I require graphical output for such things as time-domain waveforms and Bode plots. In all SPICE example netlists I strive to use coding conventions compatible with all SPICE versions.

Andrew D. Hwang’s ePiX mathematical visualization programming library

This amazing project is a C++ library you may link to any C/C++ code for the purpose of generating PostScript graphic images of mathematical functions. As a completely free and open-source project, it does all the plotting I would otherwise use a Computer Algebra System (CAS) such as Mathematica or Maple to do. It should be said that ePiX is not a Computer Algebra System like Mathematica or Maple, but merely a mathematical visualization tool. In other words, it won’t determine integrals for you (you’ll have to implement that in your own C/C++ code!), but it can graph the results, and it does so beautifully. What I really admire about ePiX is that it is a C++ programming library, which means it builds on the existing power and toolset available with that programming language. Mr. Hwang could have probably developed his own stand-alone application for mathematical plotting, but by creating a C++ library to do the same thing he accomplished something much greater.

Creative Commons License

Creative Commons Attribution 4.0 International Public License

By exercising the Licensed Rights (defined below), You accept and agree to be bound by the terms and conditions of this Creative Commons Attribution 4.0 International Public License (“Public License”). To the extent this Public License may be interpreted as a contract, You are granted the Licensed Rights in consideration of Your acceptance of these terms and conditions, and the Licensor grants You such rights in consideration of benefits the Licensor receives from making the Licensed Material available under these terms and conditions.

Section 1 – Definitions.

a. Adapted Material means material subject to Copyright and Similar Rights that is derived from or based upon the Licensed Material and in which the Licensed Material is translated, altered, arranged, transformed, or otherwise modified in a manner requiring permission under the Copyright and Similar Rights held by the Licensor. For purposes of this Public License, where the Licensed Material is a musical work, performance, or sound recording, Adapted Material is always produced where the Licensed Material is synched in timed relation with a moving image.

b. Adapter’s License means the license You apply to Your Copyright and Similar Rights in Your contributions to Adapted Material in accordance with the terms and conditions of this Public License.

c. Copyright and Similar Rights means copyright and/or similar rights closely related to copyright including, without limitation, performance, broadcast, sound recording, and Sui Generis Database Rights, without regard to how the rights are labeled or categorized. For purposes of this Public License, the rights specified in Section 2(b)(1)-(2) are not Copyright and Similar Rights.

d. Effective Technological Measures means those measures that, in the absence of proper authority, may not be circumvented under laws fulfilling obligations under Article 11 of the WIPO Copyright Treaty adopted on December 20, 1996, and/or similar international agreements.

e. Exceptions and Limitations means fair use, fair dealing, and/or any other exception or
limitation to Copyright and Similar Rights that applies to Your use of the Licensed Material.

f. **Licensed Material** means the artistic or literary work, database, or other material to which the Licensor applied this Public License.

g. **Licensed Rights** means the rights granted to You subject to the terms and conditions of this Public License, which are limited to all Copyright and Similar Rights that apply to Your use of the Licensed Material and that the Licensor has authority to license.

h. **Licensor** means the individual(s) or entity(ies) granting rights under this Public License.

i. **Share** means to provide material to the public by any means or process that requires permission under the Licensed Rights, such as reproduction, public display, public performance, distribution, dissemination, communication, or importation, and to make material available to the public including in ways that members of the public may access the material from a place and at a time individually chosen by them.

j. **Sui Generis Database Rights** means rights other than copyright resulting from Directive 96/9/EC of the European Parliament and of the Council of 11 March 1996 on the legal protection of databases, as amended and/or succeeded, as well as other essentially equivalent rights anywhere in the world.

k. **You** means the individual or entity exercising the Licensed Rights under this Public License. **Your** has a corresponding meaning.

**Section 2 – Scope.**

a. License grant.

1. Subject to the terms and conditions of this Public License, the Licensor hereby grants You a worldwide, royalty-free, non-sublicensable, non-exclusive, irrevocable license to exercise the Licensed Rights in the Licensed Material to:

   A. reproduce and Share the Licensed Material, in whole or in part; and
   B. produce, reproduce, and Share Adapted Material.

2. Exceptions and Limitations. For the avoidance of doubt, where Exceptions and Limitations apply to Your use, this Public License does not apply, and You do not need to comply with its terms and conditions.

3. Term. The term of this Public License is specified in Section 6(a).

4. Media and formats; technical modifications allowed. The Licensor authorizes You to exercise the Licensed Rights in all media and formats whether now known or hereafter created, and to make technical modifications necessary to do so. The Licensor waives and/or agrees not to assert any right or authority to forbid You from making technical modifications necessary to exercise the Licensed Rights, including technical modifications necessary to circumvent Effective Technological Measures.
For purposes of this Public License, simply making modifications authorized by this Section 2(a)(4) never produces Adapted Material.

5. Downstream recipients.

A. Offer from the Licensor – Licensed Material. Every recipient of the Licensed Material automatically receives an offer from the Licensor to exercise the Licensed Rights under the terms and conditions of this Public License.

B. No downstream restrictions. You may not offer or impose any additional or different terms or conditions on, or apply any Effective Technological Measures to, the Licensed Material if doing so restricts exercise of the Licensed Rights by any recipient of the Licensed Material.

6. No endorsement. Nothing in this Public License constitutes or may be construed as permission to assert or imply that You are, or that Your use of the Licensed Material is, connected with, or sponsored, endorsed, or granted official status by, the Licensor or others designated to receive attribution as provided in Section 3(a)(1)(A)(i).

b. Other rights.

1. Moral rights, such as the right of integrity, are not licensed under this Public License, nor are publicity, privacy, and/or other similar personality rights; however, to the extent possible, the Licensor waives and/or agrees not to assert any such rights held by the Licensor to the limited extent necessary to allow You to exercise the Licensed Rights, but not otherwise.

2. Patent and trademark rights are not licensed under this Public License.

3. To the extent possible, the Licensor waives any right to collect royalties from You for the exercise of the Licensed Rights, whether directly or through a collecting society under any voluntary or waivable statutory or compulsory licensing scheme. In all other cases the Licensor expressly reserves any right to collect such royalties.

Section 3 – License Conditions.

Your exercise of the Licensed Rights is expressly made subject to the following conditions.

a. Attribution.

1. If You Share the Licensed Material (including in modified form), You must:

A. retain the following if it is supplied by the Licensor with the Licensed Material:

i. identification of the creator(s) of the Licensed Material and any others designated to receive attribution, in any reasonable manner requested by the Licensor (including by pseudonym if designated);

ii. a copyright notice;
iii. a notice that refers to this Public License;

iv. a notice that refers to the disclaimer of warranties;

v. a URI or hyperlink to the Licensed Material to the extent reasonably practicable;

B. indicate if You modified the Licensed Material and retain an indication of any previous modifications; and

C. indicate the Licensed Material is licensed under this Public License, and include the text of, or the URI or hyperlink to, this Public License.

2. You may satisfy the conditions in Section 3(a)(1) in any reasonable manner based on the medium, means, and context in which You Share the Licensed Material. For example, it may be reasonable to satisfy the conditions by providing a URI or hyperlink to a resource that includes the required information.

3. If requested by the Licensor, You must remove any of the information required by Section 3(a)(1)(A) to the extent reasonably practicable.

4. If You Share Adapted Material You produce, the Adapter’s License You apply must not prevent recipients of the Adapted Material from complying with this Public License.

Section 4 – Sui Generis Database Rights.

Where the Licensed Rights include Sui Generis Database Rights that apply to Your use of the Licensed Material:

a. for the avoidance of doubt, Section 2(a)(1) grants You the right to extract, reuse, reproduce, and Share all or a substantial portion of the contents of the database;

b. if You include all or a substantial portion of the database contents in a database in which You have Sui Generis Database Rights, then the database in which You have Sui Generis Database Rights (but not its individual contents) is Adapted Material; and

c. You must comply with the conditions in Section 3(a) if You Share all or a substantial portion of the contents of the database.

For the avoidance of doubt, this Section 4 supplements and does not replace Your obligations under this Public License where the Licensed Rights include other Copyright and Similar Rights.

Section 5 – Disclaimer of Warranties and Limitation of Liability.

a. Unless otherwise separately undertaken by the Licensor, to the extent possible, the Licensor offers the Licensed Material as-is and as-available, and makes no representations or warranties of any kind concerning the Licensed Material, whether express, implied, statutory, or other. This includes, without limitation, warranties of title, merchantability, fitness for a particular purpose, non-infringement, absence of latent or other defects, accuracy, or the presence or absence of errors,
whether or not known or discoverable. Where disclaimers of warranties are not allowed in full or in part, this disclaimer may not apply to You.

b. To the extent possible, in no event will the Licensor be liable to You on any legal theory (including, without limitation, negligence) or otherwise for any direct, special, indirect, incidental, consequential, punitive, exemplary, or other losses, costs, expenses, or damages arising out of this Public License or use of the Licensed Material, even if the Licensor has been advised of the possibility of such losses, costs, expenses, or damages. Where a limitation of liability is not allowed in full or in part, this limitation may not apply to You.

c. The disclaimer of warranties and limitation of liability provided above shall be interpreted in a manner that, to the extent possible, most closely approximates an absolute disclaimer and waiver of all liability.

Section 6 – Term and Termination.

a. This Public License applies for the term of the Copyright and Similar Rights licensed here. However, if You fail to comply with this Public License, then Your rights under this Public License terminate automatically.

b. Where Your right to use the Licensed Material has terminated under Section 6(a), it reinstates:

1. automatically as of the date the violation is cured, provided it is cured within 30 days of Your discovery of the violation; or

2. upon express reinstatement by the Licensor.

For the avoidance of doubt, this Section 6(b) does not affect any right the Licensor may have to seek remedies for Your violations of this Public License.

c. For the avoidance of doubt, the Licensor may also offer the Licensed Material under separate terms or conditions or stop distributing the Licensed Material at any time; however, doing so will not terminate this Public License.

d. Sections 1, 5, 6, 7, and 8 survive termination of this Public License.

Section 7 – Other Terms and Conditions.

a. The Licensor shall not be bound by any additional or different terms or conditions communicated by You unless expressly agreed.

b. Any arrangements, understandings, or agreements regarding the Licensed Material not stated herein are separate from and independent of the terms and conditions of this Public License.

Section 8 – Interpretation.

a. For the avoidance of doubt, this Public License does not, and shall not be interpreted to, reduce, limit, restrict, or impose conditions on any use of the Licensed Material that could lawfully
be made without permission under this Public License.

b. To the extent possible, if any provision of this Public License is deemed unenforceable, it shall be automatically reformed to the minimum extent necessary to make it enforceable. If the provision cannot be reformed, it shall be severed from this Public License without affecting the enforceability of the remaining terms and conditions.

c. No term or condition of this Public License will be waived and no failure to comply consented to unless expressly agreed to by the Licensor.

d. Nothing in this Public License constitutes or may be interpreted as a limitation upon, or waiver of, any privileges and immunities that apply to the Licensor or You, including from the legal processes of any jurisdiction or authority.
Creative Commons is not a party to its public licenses. Notwithstanding, Creative Commons may elect to apply one of its public licenses to material it publishes and in those instances will be considered the “Licensor.” Except for the limited purpose of indicating that material is shared under a Creative Commons public license or as otherwise permitted by the Creative Commons policies published at creativecommons.org/policies, Creative Commons does not authorize the use of the trademark “Creative Commons” or any other trademark or logo of Creative Commons without its prior written consent including, without limitation, in connection with any unauthorized modifications to any of its public licenses or any other arrangements, understandings, or agreements concerning use of licensed material. For the avoidance of doubt, this paragraph does not form part of the public licenses.

Version history

This is a list showing all significant additions, corrections, and other edits made to this learning module. Each entry is referenced by calendar date in reverse chronological order (newest version first), which appears on the front cover of every learning module for easy reference. Any contributors to this open-source document are listed here as well.

23 September 2019 – explicitly added the term insertion resistance to the already-existing Tutorial discussions on meter loading effects.

19 September 2019 – minor edit to footnote in the Case Tutorial chapter.

16 September 2019 – added a Case Tutorial chapter.

26 August 2019 – added mention of difficult concepts to the Introduction.

8 June 2019 – added sub-questions asking students to apply KVL to series-parallel circuits.

22 May 2019 – added Quantitative Reasoning problem calculating the resistance of a voltmeter based on its loading effects on a high-resistance voltage divider circuit.

28 April 2019 – added problem-solving example showing a multi-source circuit completely worked through.

3 April 2019 – minor edits.

30 March 2019 – noted the existence of the “SPICE Modeling” learning modules as resources for experimenting with SPICE simulations of series-parallel circuits.

26 March 2019 – minor edits to the “Interpreting a SPICE analysis” Quantitative problem, noting at the end that SPICE is useful as a tool for creating practice problems.

16 March 2019 – added new Experiments (demonstrate KVL/KCL in series-parallel circuits).

10 February 2019 – added requirement in “Explaining the meaning of calculations” Conceptual Question to identify the principle applied in each step.

17 December 2018 – added an example C++ program showing simple series-parallel circuit calculations.

October 2018 – added explanatory diagram to Simplified Tutorial chapter showing how a series-parallel circuit may be reduced to a single equivalent component by successive reductions of series and parallel subnetworks.

September 2018 – added content to the Quantitative Reasoning section.

August 2018 – added content to the Introduction chapter.

June 2018 – finished Simplified Tutorial.

May 2018 – added more Quantitative Reasoning questions, added Simplified Tutorial. Minor edit to “parallel” illustration, annotating connected points as electrically common to each other, not just equipotential to each other.

November 2017 – elaborated on Energy versus Power conservation, and added more questions.

June 2017 – added more quantitative questions.

October 2016 – created changelog for future use.
