SPECIAL REPORT

TITLE: INVESTIGATION OF SXT ST LOS/1LOS PARALLELISM PROBLEM

REFERENCE: ENCLOSED

SITE: NAA, DOWNEY

FILE NO: NAA-6-117

DATE: AUGUST 12, 1956

Written by P. Tanner

Approved by William E. Mayo
Testing of FGNC 204 at NAA indicated several problem areas in the Block II SXT. Trunnion Positional Accuracy Test (JDC 12214). An out-of-tolerance condition (FR 14530) of +18 arc sec., which exceeded that ±15 arc sec. limits, was observed in the STLOS/LLOS parallelism test. It was not possible to correlate data from this test with any previous tests to the required degree of accuracy.

An investigation was performed to determine the cause of the problem and how this problem could be alleviated. The three main objectives of this study were to determine:

1. The actual STLOS/LLOS parallelism error.
2. If the shift in data was due to FGNC System performance changes or was attributable to the GSE and/or test methods.
3. How the SXT STLOS/LLOS parallelism error could be accurately measured and correlated with other test data points.

Five independent methods were used to measure the parallelism error (Enclosure 1). The errors of the 5" autocollimator were measured for the STLOS and LLOS for both backlit and filar (when used as a telescope reticles).

A theodolite was introduced in the SXT STLOS and the Optics Hand Controller was manipulated so as to move the STLOS to various positions while the DSKY display was maintained at +00000 Trunnion angle and +27000 shaft angle. After each movement, a measurement was taken with the theodolite. It was discovered, after twelve observations, that a 14 arc sec. envelope (Enclosure 2) was available without a change in the DSKY trunnion display.

Each of the above measurements was corrected for instrument errors and/or trunnion positioning errors (where the recorded trunnion angle could be compared with the center of the envelope of uncertainty), and then compared. The results of this comparison indicated a parallelism error of 11.5 sec. ± 0.5 sec.

The trunnion position uncertainty was sufficient to encompass all previous measurements of SXT parallelism; therefore, precise comparison cannot be made with any previous tests.

Accurate comparison could not be made between OSS, Milwaukee G&N or NAA G&N tests of parallelism, but a check of the CSS and G&N 45° trunnion accuracy tests (Enclosure 3), after resurveying the Optical targets, indicated that there was no appreciable shift of data.

In the absence of any unexplained data shift and with the poor resolution (DSKY increment of approximately 10 arc sec./bit) available it was assumed that the problem stemmed from two sources:
a. Inadequate test methods.

bb. The practice of not electrically trimming the OUA to the PGNC System. It was found that in all Optical Unit Assemblies returned to NAA from KIC and Milwaukee, after retrofit and alignment on the PTF, that adjustment of the trim module (P/N 2012568) was required. An apparently consistent misalignment of approximately 13 arc. sec. has been observed after OUA marriage to the system. Several systems have been received at NAA with OSS ST LCS/L LOS parallelism measurements that were marginal (PGNS 204 GY PARALLELISM +9 sec. tolerance +10 sec.). With known uncertainties in the OSS, GSE (AP-M-11439) and the PTF alignments (AP-M-12964), it is obvious that problems can, and have occurred at later test stages.

Investigation revealed that the Variable Deviation Wedge method of determining the ST LCS/L LOS parallelism is completely inadequate and provides no reliable quantitative measurement of this parameter. Resolution of the parallelism and trunnion accuracy test problems can be accomplished with available GSE and minimal changes in the test procedures. A TDCR (NAA-AM-437) is submitted to provide an accurate, reliable test method to check the ST LCS/L LOS parallelism at the G/N Level. TDCR NAA-AM-438 will be submitted to provide a data check point at the OSS test level, and an accurate point at which the resolver trim module may be set to position the ST LCS to the nominal. The only point, at which the correlation of the Sxt. ST LCS and the DSKY display are known with accuracy in Block II, is at zero optics; therefore, the parallelism should be measured at this point. The DKM-3X Theodolite, available at all sites, is a sufficiently accurate instrument to provide accuracy on the order of ± 0.5 seconds using the method suggested above.

Considering the data derived from this test, alignment of the resolver trim module at the OSS level with this degree of data confidence could alleviate all future problems in this area. Data correlation between AC Milwaukee tests and tests at NAA have revealed no history of ST LCS shifts on any previous system. Different test methods are used to measure this parameter in the lab and on the spacecraft, so measurements close to the tolerance limits could present problems during later tests.

1. The OSS test indicates that the trunnion measured 44° 59' 50" ± 5 sec at 45° (at 10 sec/bit). Discounting resolver functional errors this would show a parallelism error of +10 sec ± 5 sec.

2. The system test run at Milwaukee indicates the same +10 sec ± 5 sec parallelism error found in the OSS test.

3. The NAA system test showed the possibility of a data shift as the target angles were reverified with the theodolite procedure. The angle Ø 3 had shifted from 44° 59' 57.0" to 44° 59' 50.4". This would change the 45° test angle to 44° 59' 53.4". With the trunnion DSKY display of 44° 59' 40" ± 5 sec this shows a parallelism error of +13.4 sec ± 5 sec.

4. Since all three estimates of the parallelism error are within 5 sec of the actual parallelism error of +11.2 it is doubtful that a shift of any magnitude occurred in the system performance between AC Milwaukee and NAA.
Change Requested:
1. Delete steps 5 through 12.
2. Add:

5. Place theodolite in a line coincident with the Sxt. L LOS and center the ST LOS.
6. Level theodolite base to the plate spirit level and level the altitude spirit level. Adjust the telescope focus to infinity. Set telescope to approximately 90°. Install the portable light assembly and adapter in the Sxt. Eyepiece Assembly. While observing the theodolite image, adjust the G&N Mounting fixture until the Sxt. air reticle is superimposed on the theodolite horizontal filar.
7. Align the theodolite horizontal filar to the Sxt. air reticle and record the vertical angle.
8. Reverse and plunge the theodolite telescopes and repeat step 7.

Detailed Reason for Change:

See Special Report #NAA-6-117 (attached).
2. (Cont.)

9. Repeat steps 7 and 8 for seven additional pairs of readings. After completing step 8, each time drive the theodolite elevation off prior to realigning to the Sxt. reticle.

10. Place the theodolite in a line coincident with the Sxt. ST LOS and cover the L LOS.

12. Repeat steps 7, 8 and 9.

13. **Complete** calculations for Sxt. ST LOS to L LOS parallelism error.

14. Place the variable deviation wedge (VDW) in front of target number 1 and set VDW dial to zero. Sight through the Sxt. L LOS and adjust the G&N Mounting Fixture until the horizontal reticle line of the Sxt. is coincident with the dot and horizontal reticle line of target number 1.

15. Set OPTICS MODE switch on the Indicator Control Panel to M:N. Displace the Optics Controller to the left and up. Drive the Sxt. until row 1 of the DSKY indicates +27000 and row 2 indicates approximately +90000. Set the controller speed to 10 and manipulate the Optics Hand Controller to fine position and hold the Sxt. so that row 1 indicates +27000.

16. Sight through the Sxt. L LOS and move the VDW laterally until the target #1 reticle is seen clearly. Adjust the VDW dial until the central vertical reticle line is coincident with the star and vertical reticle line of the target. Repeat this procedure two additional times and record the average VDW dial reading on line (c).

3. Change item 13 to item 17 and all subsequent item numbers in sequential order.

4. Add to Data Sheet, after item 4:
